P.S.—A snowstorm last night has not improved the buds of yesterday.

### GRAPE-GROWING—INFLUENCE OF THE STOCK UPON THE SCION.

I HAVE sent you a bunch of Grapes cut from the *Madresfield Court* Vine which was some years ago inarched on a rod of the *Black Hamburg*. The length of the rod of the former was about 8 feet long, while that of the *Black Hamburg* projects about 4 feet beyond it. The *Madresfield Court* is growing in a tub, and the *Black Hamburg* in a large pot. You will see that the flavour, shape, and disposition to crack are changed. The fruit on the rod of the *Black Hamburg* projecting beyond the graft continues unchanged. I sent an account of this experiment to Mr. Darwin, who thought that the *Madresfield Court* might have been a seedling of the *Black Hamburg*, and that the latter's sap caused it to return to the original type.

At the same time that I made this experiment I also inarched another *Madresfield Court* on the common *Sweetwater*. The scion behaved in a precisely similar manner. I removed the *Madresfield Court* from the *Sweetwater*, and was surprised to find that the former for the first year produced berries similar in shape, flavour, and nature to those I now send you. There is no doubt that the saps of the two original types ride over that of the recently established seedling.—*OBSERVER.*

### EUCALYPTUS GLOBULUS.

THIS beautiful evergreen, having fine silvery blue-green foliage, is of rapid growth, the whole plant emitting a balsamic odour, and said to possess wonderful febrifugal properties. From the supposition of its capability of destroying the malarious elements in the atmosphere it has been recommended as a sanitary plant. Unfortunately, however, its value in freeing the atmosphere of malaria in this country appears, from the doubtful hardness of the plant, to be very much restricted. The efforts which have been made to acclimatise it in this country have not been very successful. It is likely, however, to succeed in sheltered situations in the south and south-western parts of the kingdom and in Ireland, from which there are reported cases of success. Except in very warm sheltered situations in the midland counties and also dry, securing sturdy well-ripened growth, little success has attended its cultivation. In the north, however, I fear it will need to be grown under glass. The west coast of Scotland may be an exception, for, being so much under the influence of the Gulf Stream, the west is much warmer than the east coast.

It has been known to be cut down to the ground by 16° of frost, and as that is much less severe than may be expected in an ordinary winter it is very unlikely that the tree will become general throughout the country. Much may no doubt be done by acclimatisation. If seeds could be perfected in this country it is likely we should have an advance towards greater hardness in the progeny, resulting ultimately, no doubt, in the origination of a hardy variety. This can only be effected by a series of experiments with the plant in a variety of situations throughout the country. I have seen it thriving luxuriantly in an orchard house unheated in the neighbourhood of Bradford in Yorkshire, and have also seen young plants cut off to the ground in an unheated house, the plants having been grown outdoors and the wood was very unripe; but if its hardness can be sufficiently established to that extent—i.e., loss of the growth made in the summer and renewed the following season, no more protection being afforded than a slight mulch, the plant becoming herbaceous, we may secure its advantages as a very handsome distinct-featured plant with possibly its malaria-destroying properties.

It is most readily propagated by seeds (which may be procured from any of the principal seedsmen) sown in March in

sandy loam and leaf soil with a little peat, and placed in a hotbed having a bottom heat of 75° to 90°. The plants soon appear, and should be potted-off singly when the second leaves show, keeping them shaded until established and growing-on in heat until May, when they should be well hardened off and planted out in June. A plant may be put out against a wall with a south aspect, another in a dry sheltered yet open situation, and others in different positions where most needed for testing their hardness and sanitary properties. In the interim information as to its hardness is solicited.—*G. ABBEY.*

### MANURING ROSES.

IN answer to the question of "MIDLAND COUNTIES ROSE-GROWER" on this subject, very much must depend on the object he has in view. If it be for exhibiting, a larger quantity will be required than for ordinary garden purposes. My object in growing Roses is that I may have under my own eye those which I am so constantly called upon to judge, and to obtain, therefore, such newer sorts as are likely to make their way as exhibition Roses. I have good flowers sometimes which I should not be ashamed to put into competition with any growers that I know; but, as I do not exhibit, cannot say that I could make up a stand. I do not, therefore, bud a quantity every year. My plants are two, three, and four years old on *Manetti* or seedling *Briars*. My soil is a light garden soil, to which I am adding some stiffer loam, and I manure as far as I can with pig manure. This I believe (sad though it may be to say so) is that which her majesty the Rose most likes. It is not so hot as stable manure, and has not so much tendency to encourage fungus at the roots, and has more strength in it than cow manure, which, however, is very good, especially in hot soils. My rule is to place it as a top-dressing on the beds in the autumn, when it seems to protect the roots from the frost, and then to dig it in in the spring.

Mr. Hole, who writes for exhibitors, recommends farmyard manure to be applied in November, and again to top-dress in June. Mr. Rivers recommends a surface-dressing in March, or cocoa-nut fibre saturated with liquid manure, and states that brewers' grains, after being fermented in a heap for two or three weeks and mixed with burnt earth, are a most powerful stimulant applied in the months of November and December, and for a summer dressing recommends a mixture of wood ashes and guano in the proportion of a bushel of the former to half a peck of the latter, quarter of a peck of the mixture to be given to each tree, letting it remain undisturbed on the surface and to be well watered in dry weather. Mr. Paul is strongly in favour of spring manuring, and recommends night soil prepared with an admixture of loam, to be placed in a pit and used after six months, either to be forked-in or scattered over the beds immediately after they are forked-in in the spring. Mr. Cranston agrees with me in considering pig manure to be the best, next night soil, and then cow dung and horse dung. Pig dung to be put on the ground during winter or early in spring, and forked-in at once.

It will thus be seen by your correspondent that in this, as in most other things, doctors differ, and he can choose from these various plans that which commands itself most to him and seems best adapted to his soil.—*D., Deal.*

### HYBRID NOSEGAY GERANIUMS.

I CAN assure "AGE" that it is not from want of trying other sorts of Geraniums that my preference has hitherto fallen on the Hybrid Nosegay section, and that as yet I have found Mr. Pearson's strain the best. I have still *Jean Sisley*, *Harry King*, *Lady Kirkland*, *Star of Fire*, *Rose Rendatier*, *Charley Casbon*, &c., but I have found it impossible to preserve every sort from *Tom Thumb* and *Stella* to *Vesuvius*, *Lucius*, &c. Geraniums are not like Roses where one can have mixed beds; nor are they, like Roses, hardy so as to take care of themselves if properly attended to when once established.

Those who like "AGE" prefer small trusses and a quantity of bloom all at one time, can of course grow *Vesuvius* and others of that stamp. I have always asserted that *Violet Hill*, where it succeeds, is still my type of a dwarf bedding Geranium, and *Charley Casbon* is nearly equally good in its way, but both these kinds require to have the old plants kept in order to have early and good blooms. No doubt in wet weather the centres of large trusses are apt to be injured, but equally so in wet weather the blooms of the smaller-trussed varieties are knocked down and disfigured.

I have only tried to give your readers the benefits of my own experience in my own garden, and can assure "AGE" I have had no interest whatever in recommending Mr. Pearson's strain other than by having found by careful selection, carried on now for many years, that they have succeeded better than any others in my garden, and nearly all gardeners and amateurs who have seen them have decided the same. I have no wish, however, to prejudice in any way the growers of other sorts of established reputation, and for pot culture I admire many of Dr. Denny's strain immensely, as well as those of some other raisers.—C. P. P.

### WINTER BEDDING.

THE objection which has been often urged against the system of summer bedding which has now enjoyed an innings of more than twenty years—namely, that it leaves the ground bare for six months of the year—should be no objection at all; the ground need not necessarily be bare for one day. The objection is obviated at once by covering the ground with spring-flowering plants, against which, however, still graver objections may be urged—we mean, against spring bedding pure and simple—the chief of which is that in most seasons it has a tendency to become more properly early summer bedding and no spring decoration at all, the plants being in their prime of bloom just when the summer bedding ought to be in hand; the ground in fact should have been for some time under preparation for those to secure a successful growth and display. Another serious objection to the popular spring bedding is that although the ground be covered with the spring plants they do present but a dreary appearance the whole of the winter; beds with bulbs only are nothing better than beds simply dug over, and the rest monotonous until the flowering period commences. And now supposing our present flower beds entirely given up to choice herbaceous plants in summer, which of course live in the ground in winter, the same objection of dreary monotony would exist.

Now we know there is a remedy for all these objections, if it were only generally practised more or less according to the capabilities of different gardens, by a liberal use of the many elegant and various-coloured dwarf shrubs now available for that purpose. Although winter bedding with dwarf shrubs is nearly as old as summer bedding, it does seem strange that it is not more generally adopted. Everybody down to the railway porter has their summer beds gay with the latest Geraniums; and although we should not expect him to indulge in coloured shrubs, we should expect to see the gaunt flower beds about a gentleman's residence made presentable in winter.

We should not propose that winter bedding be done entirely with shrubs; it would be ridiculous to ignore any one of the spring-flowering plants now in use; we rather think that their beauty would be enhanced by being judiciously arranged with the shrubs, and the effect of the whole eked out by largely pressing the hardy carpeting plants into the service as embroidery or edging. Combinations of these three classes of plants can be made exceedingly effective even in midwinter, the more striking and cheerful effects being dependant on the shrubs. Nothing will be more convincing of the cheerful effects which can be produced in winter by shrubs alone, than a walk through a well-stocked and well-appointed nursery where the various shrubs are grown in large groups and quarters. The colours among Euonymuses alone are very varied and striking—from bright yellow in *E. latifolius aureus*, through various shades of yellow, silvery grey in *argenteus elegantissimus*, and nearly white in *radicans variegatus*. Among *Retinosporas* are also several effective shades of colour, the silvery grey of *squarrosa*, red of *ericoides*, and yellow of *plumosa aurea* and *pisifera aurea*. The forms and colours in *Cupressus Lawsoniana* are now become very various and distinct (colour is what we have most to consider at present, from dense dark green to light green and glaucous): Waterer's variety of *C. argentea*, *C. albo-variegata*, and *C. aurea variegata*, and there are yet other varieties of hoary grey colour after the manner of the colouring of *Thuja Vervaneana*, which are exceedingly well adapted for winter bedding. Boxes and Hollies furnish a large variety of effective bedding shrubs in themselves. The gold and silver varieties of Holly require no recommendation; they are not expensive in the young state, and one circumstance in their favour is that they bear moving in April, if it be not the very best month in which to move Hollies. It is not our purpose to mention by name all the many plants fit for winter bedding—many more, we are aware, could be employed here

in the south than to the north of London; but *Ericas herbacea* and *vulgaris aurea* deserve to be specially mentioned, also the numerous varieties of *Vincas* and *Ivies* as being so easily propagated at home.

In massing beds for winter one or more varieties of shrubs may be used for the centres, to be banded round by such of the spring bedding plants as may be decided on for contrast, such as *Myosotis*, *Arabis*, *Belvoir Castle Wallflowers*, or *Pansies*. Or a bed may be filled entirely with shrubs, the centre of the larger-growing sorts banded by *Heaths*, *Euonymuses*, *Ivies* of any dwarf trailing sort, mixing the dwarfier shrubs alternately with *Hyacinths*, *Tulips*, or other spring bulbs, so that the ground may not be at any time bare, and yet the effect of the bulbs be enjoyed in spring. Large beds may still further be embroidered by the different *Saxifrages*, such as *hypnoides* and other bright green sorts, or the white crusted sorts and the different coloured *Sedums*. *Daisies* work well in with the *Sedums* and *Sempervivums*, and when in flower look neat and showy in rays and scollops round large beds. *Daisies* and all the sweet *Violets* are making an early autumn effort at bloom this season: even the Neapolitan Violet is as full of bloom as if it were March; that is, however, premature and peculiar to the season—the dull days of December will check them.

The chief reason why winter bedding with shrubs is not more largely carried out is probably the fear of the first expense. A large stock of useful-sized plants would no doubt involve a considerable outlay, and but few would launch into that expense at once for a large garden. They are not exactly the gardener's plants to be increased by thousands without any apparent expense to the employer in a few months; they may, however, be as easily and readily propagated as bedding plants with the proper means, though not so quickly grown into size; when once propagated they are not so fugitive as ordinary bedders—they remain serviceable for years. Some can be increased by division very readily, such as *Erica herbacea*, *Retinospora ericoides*, *Vincas*, *Euonymus radicans*, *Ivy*, various sorts of low dwarf *Rhododendrons*, and even *Thuja* and *Cupressuses*; very many can be raised from cuttings under hand-lights or in cold frames in autumn, such as all the broad-leaved *Euonymuses*—in fact all the broad-leaved Japanese plants, as *Aucubas*, the Japanese *Retinosporas*, *Thuja*s, *Cypresses*, and many of those softwooded shrubs, strike readily from cuttings. The same amount of care which is required to propagate many of the summer bedders will be equally successful with these if a fair trial be given them. Shade from bright sun, and the moisture of a cold frame with frost excluded, are the best conditions for success, inserting the cuttings firmly in sandy peat. Variegated Hollies are often propagated in this way, although grafting is the usual mode. The difficulties of propagation are not so great as to prevent a satisfactory effort being made with the view to so desirable a result as the acquisition of a cheap and useful stock of winter bedders. When dwarf shrubs are removed from the beds in spring, a cool moist situation should be devoted to them in which to grow them for the summer. Any light sandy soil will suit them if not too much impregnated with manure; in stiff clay soils they do not generally do so well, and where such exists a piece of ground must be prepared for them. The frequent removal keeps them dwarf, and encourages a mass of roots close at home. No better time could be chosen than October for moving in autumn, the month when the work must be done; and again in spring no better time could be chosen than April, the month when the same work must be done. We are aware that these matters of soil will be a serious drawback with many. A dry draughty situation is also a difficulty not easily overcome; an elevated inland situation where the winter is severe, is unfavourable to the cultivation of the better class of Japanese shrubs; but to those so situated we say there are plenty of subjects suitable for the purpose, though the choicer must be avoided, and after all we think even these are but few.—THE SQUIRE'S GARDENER (in *The Gardener*).

### MADRESFIELD COURT GRAPE CRACKING.

I WAS much interested by the remarks on page 388 respecting what is called the "besetting fault" of this superb Grape, and of its alleged demerit of conveying this evil propensity to the scions of other varieties. From these conclusions of our Irish friend I decidedly differ.

I have growing in the same house several Vines of *Madresfield Court* and *Gros Colman*.—The former has finished its

bunches, as in previous years, to perfection in size, colour, bloom, and flavour without a berry bursting; but the majority of the berries of Gros Colman burst their skins shortly after the commencement of colouring (many of these berries were as far round as a penny-piece). This defect I can now see arose from my having removed the mulching from the border to accelerate the ripening of the fruit when several weeks of parching drought was succeeded by copious rains. The consequence was, this gross-feeding variety gorged itself with the suddenly-supplied sap, and the berries split. Most of the Plums outdoors did the same. I take it that judicious mulching and watering will always prevent Madresfield Court from bursting its skin, and I am confirmed in this opinion by the significant reply of the Editors of this Journal to an inquirer. After explaining the cause of the defect they add, "Our Grapes never split."—A NORWICH GRAPE-GROWER.

### METROPOLITAN FLORAL SOCIETY.

In last week's Journal "*D., Deal,*" expresses surprise at a statement made by me in a previous one in reference to the above-named Society, and I cannot allow his remarks to pass unnoticed. He says I thought the Society "with an empty exchequer ought to have offered prizes and arranged for an autumn show this year." Now, I never thought or said anything of the kind. What I thought and might have said is this: That it would be as much to the interest of the Alexandra Palace Company to hold a show in September for flowers and fruits, as it would be for the same Company to hold one later in the year for Potatoes only. Perhaps I also said that the same Company might have been disposed to encourage the Metropolitan Floral Society if it was worked on the same principle as other societies, including that for the encouragement of the Potato. All of them have rules which admit of the election of a president, vice-presidents, treasurer, secretary, &c. Now, I did write to the Hon. Secretary of the Metropolitan Floral Society, suggesting that we try to get a few influential names to fill those important and essential offices, to which letter I received a "mind your own business" reply. I certainly did do so, by neither answering the letter nor interfering further.

Just one word about a national Auricula show. The northern growers will come to London next year, and meet their brethren in the south in friendly rivalry. They ask for no guarantee of £20, but they leave it in our hands to make all arrangements; and we do hope, notwithstanding the "discount" at which florist flowers are held, to offer prizes to the amount of £50.—J. DOUGLAS.

"*D., Deal,*" says (page 407), referring to the exhibition of Carnations and Picotees at the Royal Horticultural Society's gardens in July last, "there were just five exhibitors—three from the neighbourhood of London, one from Ipswich, and one from Bath—a very poor foundation on which to rest a hope of a revival of the taste."

He further tells us the National Auricula Society will not come to London "unless some Society guarantees them £20," and in another paragraph he is good enough to inform us "florists' flowers seem hopelessly at a discount in the south." Permit me to say the exhibitors of Carnations and Picotees at the Royal Horticultural Society's July Show were seven—viz., Mr. Charles Turner, Mr. Douglas, Mr. Hooper, Mr. Cattley, Mr. Hines, Mr. Buxton, and myself.

His statement as to the purpose of the members of the National Auricula Society is also incorrect. I have been in repeated communication with the Honorary Secretary of the Society and various of the principal supporters since August, and not one word has passed as to £20 or any other sum. I know our northern friends have confidence in their southern brethren, and they will come (I undertake to say this upon my personal responsibility) not to contend for £20—the prizes will be twice or thrice that amount at least—but to demonstrate their devotion to floriculture.

To "*D., Deal,*" "florists' flowers may seem hopelessly at a discount in the south," but I speak from a much longer and wider experience than he can lay claim to, and he must be very unobservant who cannot see at the present moment palpable signs of a wide and lively interest rapidly extending for florists' flowers.

"*D., Deal,*" says of the Carnations and Picotees at the Royal Horticultural Society's Show above referred to, they "were fine... according to the *present* notion." I italicise the word "*present*" simply to say that "*D., Deal,*" can point to no period

since the Carnations and Picotees have been subject to the florists' care and objects of his regard, when flowers such as were there shown in the winning stands and in one or two which did not win would not have been thought fine. If "*D., Deal,*" proposed to take exception to the flowers then shown in contradiction to the terms of his report in your number for July 20th, it would be more in accordance with candour that he should do so openly rather than suggest the thought by the assertion that they were "fine according to the *present* notion."—E. S. DOWELL.

In my observations on this subject in last week's Journal I made a mistake, I find, as there were seven exhibitors, not five, of Carnations and Picotees at South Kensington in July, but it does not appreciably alter the matter. The National Auricula Society will not hold its Show in London, but I find that a promising effort is being made to hold a national show on April 25th at the Regent's Park, which I trust may succeed.—*D. Deal.*

### USEFUL APPLES.

"WHAT varieties of Apples are best for the months of April, May, and June?" is doubtless an important question, for good Apples in those months are always scarce and dear, and occasionally they can only be had at prices which are quite prohibitory to the great majority of those who covet a supply of this useful wholesome fruit.

While I trust that valuable information will result from the above reasonable question, I can hardly agree with "WILTSHIRE RECTOR" that medium-season Apples should be overlooked simply because "there are plenty of those to choose from." In my opinion that is not so much an argument in favour of non-discussion on the merits of Apples coming into use, say from October until February, as a circumstance suggesting that special care is requisite in selecting kinds which are the most useful for those seasons. If we examine large plantations or orchards of Apples we find that in most of them some mistakes have been made. A very common mistake, which has been previously pointed out, is the omission of an adequate number of summer Apples. Another mistake, and one arising from the fact of there being "so many sorts to choose from," is that much ground is occupied by varieties which are not in the best degree profitable. My experience has taught me that one of the most difficult points to decide by planters of fruit trees, and especially by those who are young and enthusiastic, is the leaving-out of sorts which are included in lengthy catalogues, and where almost every sort is credited as possessing some special virtue. It is in the great mid-season of the Apple period where careful discrimination is especially required, when it is desired to occupy ground in the most useful and profitable manner, so that the greatest advantage will result to both producer and consumer, for there is a natural alliance between the two which must not be ignored, and what is best for one is also best for the other.

Not all growers, however, plant trees with the one object of producing merely a profitable and serviceable supply of fruit; but plant with the object of deriving pleasure from the possession of a great number of varieties, and which will produce fruit adequate to their purpose. But beyond these, what may be termed fruit fanciers—a most laudable fancy—there are an infinitely greater number who wish to have the most reliable information possible on the varieties which are the most really useful. Long lists are referred to, but these only add to the perplexity of those who are devoid of experience, and hence it is during the period when varieties are the most numerous that discussion becomes the most necessary and is the most welcome. I would not, therefore, have the mid-season sorts passed as unworthy of discussion.

"WILTSHIRE RECTOR" himself affords proof that a little interchange of opinion is needed on mid-season Apples, and cannot resist speaking in terms of admiration of one which he appears to set up as an example of his desideratum—beauty with utility. That variety is the Emperor Alexander. That is undoubtedly a handsome Apple, and the tree is a good bearer. It is particularly suitable for growing as an espalier, being too luxuriant for bush culture, and on standards in exposed places its fruits become bruised if not blown off by the winds. It is an excellent culinary Apple, but (and exceptional "buts" are often of considerable importance) it is perhaps the lightest of all Apples, and on that account I do not consider it one of the most useful and profitable to

cultivate. I would include it for such positions as it occupied in the garden referred to, but would not urge its being largely planted for supplying the markets with fruit, or for giving the best returns to the grower. What I mean is this—that "WILTSHIRE RECTOR" might plant it as an espalier in his garden to produce fruit for his own use and admiration, but if he desired to plant Apple trees to produce fruit for selling to his parishioners he can find other varieties which would be better for him and for them.

Our friend refers also to another Apple that has been frequently noticed—the "Greasy Coat"—as not, as he knows it, being good. I have very little doubt that the "book name" of Greasy Coat has transpired in the recent correspondence, and that it is the Transparent Codlin, which is a really good culinary Apple; few better in its season. It should be grown as an espalier or orchard tree, it being too spreading for dwarf bush cultivation. Its fruit, although large, is not nearly so much bruised by the wind or blown off the trees as is fruit of the Emperor Alexander, and Transparent Codlin is therefore suitable for growing as an orchard tree.

Large Apples as a rule are not the best for growing as standards, but there are a few the fruit of which is not only firm in itself but is also firmly affixed to the trees. A large Apple of this character is the Alfriston, which is in use from November till April, and is a very valuable kind. It does not usually produce a prodigious crop one year and little or no fruit the next, but is a useful steady bearer. I have seldom found it to fail in producing a profitable supply of fruit.

Another Apple which, in my opinion, deserves honourable mention as combining in a high degree "beauty with utility" is Beauty of Kent. It is in use from October to February, and it is as handsome as it is good for culinary purposes. On the Crab stock the tree grows very freely, sometimes vigorously; and on the Paradise stock in good soil the growth is sufficient, and the crop of fruit is almost invariably good. In some districts I have heard that trees on the last-named stock are prone to canker, but I have never been troubled with that disease affecting this variety, but I have been rewarded with splendid fruit from ornamental pyramid trees. I have found the fruit more highly coloured from the Paradise than the Crab stock; but on any stock and under any mode of culture—standards, pyramids, espaliers, and horizontal cordons—I consider Beauty of Kent to be one of the best of culinary Apples. It only fails when all others fail from the effects of severe spring frosts, to which, however, it is one of the last to succumb. Were I making an extensive plantation of Apples I should grow trees of this kind by the dozen, in confidence that the fruit would prove its worth in satisfying the public and myself. I commend this Apple to the notice of "WILTSHIRE RECTOR," and all others whom it may concern, as being very valuable as a free bearer, also beautiful and good.

I have one more Apple to bring to the notice of our friend as also combining "beauty with utility"—namely, Cox's Pomona. This is a splendid Apple, and excellent for culinary purposes. The tree bears freely in a small state, and its crop, either on cordons, bushes, or espaliers, is extremely handsome. It was raised I believe by Mr. Cox, of Cox's Orange Pippin fame, and I cannot consider any garden complete which does not include these two sterling varieties in its collection.

The few varieties named are outside the list requested by "WILTSHIRE RECTOR," but they are good, and others are also good of the same season, a season above all others where discrimination is particularly necessary on account of the immense number of sorts which annually puzzle many who anticipate planting few or many trees. I should be glad to have other mid-season varieties of special merit pointed out, and, if time permits, I will on a future occasion give attention to the sorts which are "best for the months of April, May, and June."—A MIDLAND COUNTIES FRUIT-GROWER.

#### WINTER SARRACENIAS.

THE different species of *Sarracenia* have of late become better known and more interesting to cultivators and amateurs since their insectivorous propensities have been so prominently brought before the public by Darwin, Hooker, and others. Their principal value is, however, generally associated with this peculiarity and their curious side-saddle flowers in summer. Few, even among plantmen, have any idea or knowledge of the marvellous leaf beauty of some of the species in winter when well grown. At the present moment the large purple pitchers of *Sarracenia Drummondii* and its white variety

*S. Drummondii alba*, are among the most showy and striking objects in the conservatories at Glasnevin. Without seeing them and gazing on the beautifully painted transparencies—for such like are the spreading lids and upper portion of their singular leafy tubes—it can hardly be believed how showy they are when grown and developed as they are at Glasnevin, where the average height of the pitchers varies from 18 inches to 2 feet.

If we are not mistaken, to Dr. Moore attaches the credit of being the first to effect a cross between species of this singular and very interesting genus. The parent plants he selected to manipulate with were *S. Drummondii rubra* and *S. flava*. The result was a truly grand cross, quite intermediate in aspect and character with its parents. Its peculiarities are that the coloured winter pitchers are not so bright as are those of *S. Drummondii*, but very different from those of *S. flava*. The latter, be it remembered, too, does not make winter pitchers; whereas those on the hybrid at present are of quite recent growth, 2 feet or more high, and stout in proportion. It seems to us to be unquestionably the finest.—(*Irish Farmers' Gazette*.)

#### ANCHUSA CAPENSIS (THE CAPE ALKANET).

I RECEIVED through the courtesy of Messrs. Carter & Co. of High Holborn this spring some seeds for trial, and amongst them was this, which promises to be a most useful addition to our perennial plants. It is vigorous-growing, but not rampant, with lovely blue Forget-me-not-like flowers, and has bloomed continuously from May to the present time, the flowering shoots being cut off as they decayed. I presume it is hardy, for it has not been in the least affected by the sharp frosts we have had; if so, it will be a real acquisition.—D., Deal.

#### THE OLD MARKET GARDENS AND NURSERIES OF LONDON.—No. 13.

A WRITER in a popular journal has lately commented upon the partiality for floral adornment which prevails in the districts he calls Tyburnia and Westburnia. I do not know whether there is anything in the appearance of these districts which entitles them to be regarded as exceptional, for it is satisfactory to find a taste for flowers is tolerably general in our London suburbs. In St. John's Wood, adjacent to the above-mentioned places, flowers are also much the fashion; and if we are to credit the axiom that wherever people are interested in the culture of flowers they cannot be irreclaimably bad, this much-scandalised district may not deserve all the censure that is applied to it. Like a well-known western suburb, St. John's Wood has a bad name, yet there cannot be a doubt that there are hosts of persons of good repute living in it, nor can you by any contrivance exclude queer folks from a locality. Evidently, however, the trade of florist is a good one in Paddington and St. John's Wood, though only a small proportion of the plants sold there are grown on the spot. The district was not one remarkable for its nurseries in the reign of George III., when other districts, such as Chelsea, had flourishing establishments, and the reason was the scarcity of residents in the neighbourhood likely to be purchasers of plants. When Nightingale wrote his history of London in 1815 he notified the fact that Paddington was beginning to increase in size, though it grew slowly in importance, since the houses built were chiefly of a mean sort; and an account of Paddington written twenty years earlier informs us that of about 1200 acres of ground belonging to the parish, only eighty-four were under cultivation, and as we know houses were scarce then, the rest was doubtless used for pasturage.

Going back a good many years we find evidence that a good deal of this part of north London was woodland, though the precise date when it was cleared is not determinable. Hyde Park to the south was a portion of the same forest or wood, a curious reminiscence of which is extant in what poor Tom Hood the older calls "that bare wood St. John's." There was, after some clearance had been made, a wood which was the property of the Knights of St. John, and as they had also another wood at Highbury named "Little St. John's Wood," some slight confusion has arisen. The soil here, though clayey, yielded less water than the land farther west, where the character of the ground is shown by such appellations as Kiburn, Tyburn, Westbourne, and Bayswater. By degrees St. John's Wood was cleared of its timber, a few trees, chiefly Elms, only remaining to tell the story of other days, and cows fed here peaceably, as in the adjacent districts of Paddington. A proof

of the presence of many cattle is furnished by Lyson's remark, that the ground was much of it "factitious" from the manure that had accumulated. Some of the farmers probably grew a few vegetables for the London market in the Paddington fields as far back as 1800; and from an "old inhabitant," whom adverse circumstances have brought to the level of a crossing-sweeper, I am informed that there were several "big orchards" at St. John's Wood and Maida Hill, which were to be seen some thirty years since, the trees, it may be presumed, planted early in this century, when London received most of its fruit from its immediate neighbourhood. Neither in Bayswater nor in St. John's Wood were there nurserymen known to fame in those times when the Dutch gardeners gave an impetus to flower-culture, though it is likely, had there been such, the district would scarcely have retained them for any length of time.

Local historians are mostly eloquent about the beauties of the mansion and grounds known as Westbourne Place, with a history reaching back to the days of Henry VI., but dating their beauty from their acquisition by Jukes Coulson a century since, who obtained the services of some of the best gardeners of that day. As his name, however, is not associated with the progress of horticulture it would appear that he did little more than render his grounds attractive to the eye. Still more renowned, though with a dubious fame, was Sir John Hill, a near neighbour of the owner of Westbourne Place and a medico-botanical quack, who had a following of credulous admirers. His books and pamphlets are never read now, save by those who may be studying the history of one who was half crazy, half a charlatan; and it is only needful to notice him here because he had a kind of nursery at Bayswater, in which he cultivated plants for his decoctions and distillations. If he had lived in this age he might have advertised freely, and so secured a good income from his "Water-dock Essence" and "Balsam of Honey;" but his repute speedily declined, and his medical garden was turned into a tea garden, becoming a popular resort for some years. As we are told that he selected the locality because it was peculiarly fitted for the culture of aquatic plants, it could not have been a very healthful spot, and probably where Hill once professed to cure diseases people afterwards caught ague and rheumatism. On land now covered with splendid mansions, and in proximity to Kensington Gardens, looking over the Uxbridge Road, there was a small market garden extant, if I remember aright, about twenty years ago or less. It was, I think, situated on the slope of the rising ground called Craven Hill, and where, according to a generally received belief, Earl Craven set apart land for the burial of any future victims of the plague. Eligible as the place was for a market garden, it was so much more eligible for the builder that it was soon seized upon when Bayswater grew with rapid strides after the Great Exhibition of 1851.

At the time numerous coaches ran along the Edgware Road the Pine Apple Nursery of the Messrs. Henderson would be a matter of remark, indicating that Maida Hill was reached, and that Kilburn was not far distant. There is, I presume, no doubt that it received the name it still bears from the fact that the Pine Apple was grown here successfully and largely also, but the establishment was not the one to which belongs the credit of having initiated the culture of this fruit. It was in the garden of Sir M. Decher at Richmond, Surrey, that the first English Pines were produced in 1718. Subsequently the London nurserymen made sundry improvements in the mode of culture, and even grew Pines freely in the open air with certain precautions. But as the atmosphere of the metropolis became more smoky it was necessarily unfavourable for a plant which London asserts needs above all things free ventilation to its leaves both under glass and when exposed. The present proprietors of the Pine Apple Nursery are unable to give such particulars concerning it as would fix its date, but from the history of the neighbourhood generally it may be conjectured to be not more than forty years old. At one period, writes the author of Bohn's "Handbook to London," this nursery was famous for its Heaths, and Vines were also paid much attention to; subsequently it was in high repute for forced and various greenhouse plants ere it was surrounded by a number of rival establishments. Probably from the demand for their plants being so considerable the Messrs. Henderson were induced to acquire another piece of ground in the Wellington Road, St. John's Wood, where they have produced many valuable and curious plants, as recorded in a short descriptive paper published in this Journal a year or two ago. Following the Messrs. Henderson we have the name of Weeks associated

with the nursery for a short period, but that name is better known in the regions of Chelsea.

A brief mention must be made of Maida Vale on the London side of the Pine Apple Nursery, because there a little cluster of nurseries is observable; and if they are scarcely to be called "old," they are memorable as, taken together, they form a pleasant reminder of bygone days when the Vale was rural, and also in such a suburb their existence may be but brief. First, moving northwards, we come upon the Clarendon Nursery, long occupied by the late Mr. Videon, from whom I might have obtained interesting information regarding the locality had he been living. His nursery, though moderate in size, was well planned out, but very probably, as a sale of the stock is pending, ere long the ground will be a prey to the builder. Adjoining is the nursery of Mr. McArthur, of less extent, and then we pass some private residences to come upon four more nurseries, Mr. Fairnington, who aspires to the dignity of being a landscape gardener as well as a nurseryman, having very suitably the largest plot of ground. The nurseries of Messrs. Titcomb, Fozard, and Pollett do not require anything to be said about them beyond the observation that no effort seems to be spared to utilise space, so that the gardens are not available, nor perhaps intended, for promenade. Also I was amused to perceive that there were growing within easy reach of by-passers, in so frequented a thoroughfare as the Edgware Road, Vegetable Marrows and other vegetables which might well prove tempting to the irrepressible London boy, who is seemingly better trusted in this district than in some others.

There is another nursery not very far off, yet which is so situate that many persons might wander about St. John's Wood and fail to discover it. This is in the Garden Road, a turning out of Grove Road, and is held (or was so until recently) by a Mrs. Ginn, who must be ranked therefore as a "nurserywoman." My "old inhabitant," whose memory was better than his descriptive powers, recollected the ground, which was then covered with fruit trees principally, being partially cleared for the erection of greenhouses, &c., something like thirty years ago; and confirmatory of his date was a line of trees on the north side of the ground appearing of about that age, and evidently planted as a screen from the north winds. Since a good part of this nursery already lies waste and yields a plentiful crop of weeds, the remainder will probably not be cultivated much longer, particularly as streets close by are shutting out the air and light.

Crossing the Edgware Road and going in the direction of Paddington we come rather unexpectedly upon a largish open space in proximity to the Elgin and Portsdown Roads. It formerly belonged to Paddington farmers, who could scarcely be termed "gardeners," though they sent some vegetables as well as milk to the London markets. On a strip of this land are to be noticed a number of small carefully tended gardens, with quaintly contrived huts or sheds for the purpose of holding tools, and here and there a home-made frame. These are allotment gardens, where working men spend time in wholesome employment which might otherwise be dissipated in the public house, and this excellent movement ought to receive the hearty support of all of us, certainly of those who are on a larger scale occupied in horticulture.—C.

## STRAWBERRIES IN NOVEMBER—GARIBALDI.

"MR. BENNETT, Rabley Gardens, Herts, sent a pot of Viscomtesse Héricart de Thury Strawberry, under the name of Garibaldi, full of fruit." That extract I make from your report of the Fruit Committee of the Royal Horticultural Society, and which is an authoritative ratification of rumours which have become somewhat common that Garibaldi is not a distinct variety. I saw the plant referred to above, which was bearing a good crop of nearly-ripe fruit, and I know that Mr. Bennett has been lately sending fine ripe Strawberries to Covent Garden, and obtaining "long prices" for them.

A Strawberry bearing so freely and ripening so well in the late autumn months is unquestionably an acquisition, and most gardeners would be justly proud of placing dishes of well-coloured fruit on their employers' tables in October and November, and it is certain also that those Strawberries would be appreciated. It is valuable to know that Garibaldi will bear fruit freely thus late in the season, but still more valuable to find (if such be the fact) that Viscomtesse Héricart de Thury will do the same. Plants under the French name are to be found in most nurseries and gardens, but plants under the Italian name are not nearly so easily procurable.

My own opinion is, and I express it diffidently, that Garibaldi is not the same as Viscomtesse Héricart de Thury. I have grown them both side by side, and the former had, in my case, rounder foliage with shorter footstalks, also shorter fruit stems and rounder fruit than the latter. Garibaldi, with me, was more compact in habit than the "Viscomtesse," and although both produced fruit in the autumn, Garibaldi produced it the more freely.

I remember when visiting in Lincolnshire a few years ago admiring a wonderful border of Strawberries in the gardens of Blankney Hall. It was late in October, and the crop then ripe was almost if not quite as fine as crops usually are in July. Mr. Frisby gathered dishes regularly for dessert, and I think he told me he did so every year with the same variety similarly treated. The plants which were fruiting so freely in the autumn had been forced in the spring and afterwards planted out in rich soil in a cool situation. I know that plants of Keens' Seedling will occasionally produce fruit in the autumn after having been forced and planted out, and that more certainly will Viscomtesse Héricart de Thury, but I have not found either of them so constant in this respect as Garibaldi. I do not now force Strawberries, but if I did I should rely on this variety as not only one of the earliest, but also—which is equally valuable—as being the latest Strawberry in cultivation.

It would be useful to know if Mr. Frisby still grows Garibaldi and if he considers it identical with Viscomtesse Héricart de Thury, also if Mr. Bennett is of the same opinion. A solitary plant in a pot is not sufficient to enable a decision to be arrived at; and although the members of the Fruit Committee may and doubtless have had practical experience with Strawberries having these names and had proof that they were synonymous, yet that does not quite prove enough, for they may not have grown the veritable "Simon Pure," the true Garibaldi.—A RETIRED GARDENER.

#### WEST'S ST. PETER'S GRAPE.

I HAVE often wondered why it is that this Grape is not more grown than it is. I believe it will not be found in one vineyard out of every hundred at the present day. It was always a favourite with me, and it is to my mind the most refreshing and agreeable Grape grown. It has, moreover, come under not only my own but many others' observation, that invalids have decidedly preferred it to any other Grape, which is a good criterion of its highly refreshing and thirst-satisfying qualities. For this alone I contend that my favourite should be thought more of than it is, for I believe that half, and more than half, of the Grapes grown or kept after this season are eaten by invalids. It is well known that Lady Downe's is very agreeable, and has a very refreshing quality about it; but its hard skin is oftentimes an objection to the invalid, while West's St. Peter's cannot be objected to on that score, for it has a very tender skin. I intend making a new plantation of it this year, and I hope those who have Vines to plant will bear this variety in mind, and I am convinced they will not regret having planted it. Of course it is not a sensational Grape, and can scarcely be called an exhibition Grape, but it is strictly an eating Grape, and above all an invalid's Grape, and it will hold its own against all comers.—K.

#### THOMAS ANDREW KNIGHT.

THIS well-known pomologist and first President of the Royal Horticultural Society was the younger brother of Richard Payne Knight, the writer of many observations on "Taste." They were the sons of the Rev. Thomas Knight of Wormsley Grange in Herefordshire, and where the subject of our notes was born on the 10th of October, 1758.

"My father," said Mr. Knight in a communication to us, "was a man of much learning and acquirements. Having great power of mind, and living in an extremely quiet and sequestered spot, he was supposed by his ignorant neighbours, in their language, 'to know everything.' He died at an advanced age, when Mr. Knight was an infant, and as evidence of the respect his knowledge obtained him, whenever in childhood his son sought for information upon any unusual subject, he was told 'that his father would have answered him, but that nobody now could.' " "Being born in the midst of orchards I was early led," continues this distinguished horticulturist, "to ask whence the varieties of fruit I saw came, and how they were produced. I could obtain no satisfactory answer, and was thence first led to commence experiments, in which

through a long life of scarcely interrupted health I have persevered, and probably shall persevere as long as I possess the power." The "Athenæum" epitomised as follows the chief of his scientific services.

When young Mr. Knight's education was so much neglected that when, at the age of nine years, he was sent to school at Ludlow, he was scarcely able to do more than read. But the days of his childhood had not been passed without employment. He had a great turn for the observation of natural phenomena, and having been left to occupy himself in the country in what way he pleased, he had already formed a close practical acquaintance with such plants and animals as Herefordshire could furnish. Eventually he graduated at Balliol College, Oxford, and subsequently occupied himself with researches into various points of vegetable and animal physiology. One of the most remarkable of his early investigations was contained in a paper read before the Royal Society in 1795 upon the inheritance of disease among fruit trees, and upon the propagation of debility by grafting. The county of Hereford had long been celebrated for the produce of its orchards, and the cider made therefrom was in high esteem; but towards

Fig. 64.—Mr. T. A. Knight.

the latter part of the last century the trees of the most esteemed sorts, which had been eulogised by the county poet Philips, became gradually less productive, their vitality being nearly exhausted. Still the old practice of grafting young stocks with the debilitated shoots of these trees generally prevailed, till Mr. Knight, after a long course of interesting experiments, satisfied himself that there is no renewal of vitality by the process of grafting, but merely a continuation of declining life, and that young grafted stocks soon became as much diseased as the old parent trees. He then commenced a course of experiments by fertilising the blossoms of some hardy Crabs or Apples with the pollen taken from the flowers of the most celebrated dessert and cider fruits, and sowing the seeds thus artificially impregnated. From that time Mr. Knight was looked up to in this country as a vegetable physiologist of a high order, a character which he ably sustained by various experimental researches into vegetable fecundation, the ascent and descent of sap in trees, the phenomena of germination, the influence of light upon leaves, and a variety of similar subjects. In 1797 he published a small work called "A Treatise on the Culture of the Apple and Pear, and of the Manufacture of Cider and Perry;" in which he recommends raising new kinds from seed, and suiting the sorts produced to the peculiarities of soil and climate, which are found to have so great an influence on the quality of cider. Mr. Knight did not confine his experiments to the improvement of the Apple only, but he raised many Pears most valuable for the dessert, and so hardy as not to require the warmth and shelter of walls, and consequently capable of being cultivated by every farmer and cottager in the country. His seedling Plums, Strawberries, Nectarines, and Potatoes are also of great value, and an important addition to the luxuries and necessities of life.

The great object of this distinguished man seems to have

been in all cases utility. It was chiefly to questions which he thought likely to lead to important practical results that his attention was directed, and the numerous papers communicated by him to the Transactions of the Horticultural Society, in the chair of which he succeeded his friend Sir Joseph Banks, have all this distinguishing feature. No one who has traced the progress of horticultural skill for the last twenty or thirty years can be ignorant that it is mainly due to the writings and practice of Mr. Knight; he was probably the best practical gardener of his day. It is, however, not a little remarkable that with so very extensive a knowledge of the facts of vegetable physiology, he should have been so unfortunate, as he certainly was, in many of his explanations of them. This arose no doubt from his unacquaintance with vegetable anatomy, and consequently with the minute means by which Nature brings about her results in organised matter. Mr. Knight's experiments were not confined to vegetable physiology. He was a close observer of the habits of animals, and one of his last communications to the Royal Society was on the subject of animal instinct. At a late period of his life he also made some attempts to improve the breed of draught horses, by crossing the large London dray horse with the strong and compact Norwegian mare, the result of which was not ascertained at the time of his death, but was expected, from the appearance of the colts, to be attended with success. He died in London on the 11th of May, 1838, in the eightieth year of his age.

### APPLES.

I LIVE in an Apple-growing county, Devonshire, and can truly say if you go to a grower he often gives his trees some high-sounding name, while what you buy turns out worthless. As a man cannot expect to plant often during a lifetime, this carelessness about names and kinds is much to be regretted.

Some Apples in our older orchards excel the new kinds which are much cried up. Among them are the Priory, the Buffcoat, the Onion Apple, and others. Truth in names and kinds seems to be a desideratum. It seems to me the Apple, as being among the best-flavoured as well as nutritious of fruits, is well deserving notice; and as the food question gains ground I should not be surprised to see this fruit take an important position.—T.

### ROSES ON A NORTH BORDER—CUTTINGS.

I SHOULD certainly advise "ST. EDMUND" to transplant his "own-root Roses" from the north border where they at present are to a more genial soil with a sheltered aspect, say south or east; if he has not a wall some sort of fence or shelter should be made to protect them. This is by far the best time for transplanting, as the Rose trees become half established before severe weather sets in. I should plant them in rows about 15 inches apart.

Certainly no other kind of plant should ever be suffered to grow near dwarf Roses. I should not recommend him to take his two Tea Roses indoors for the winter. I do not at all approve of moving Teas more than is absolutely necessary. Perhaps his soil is too heavy for Teas. If so he had better lift them and place a compost of turfy loam and old hotbed manure on the bed that he means to fill with Teas, prune the roots, and plant with care. If these two Teas are on the Briar he must be careful not to plant them too deep. *Souvenir d'un Ami* is a capital grower here, but I know nothing of *Madame Falcot*, except that her eyes are exceedingly large and that she is perfectly worthless as an exhibition Rose, but her buds are most valuable for bouquets or button-hole flowers.

In reply to "IRIS" about "putting in Manetti" cuttings now, taken "from standards budded in August," I never heard of a Manetti cutting from a standard Rose, and so cannot possibly advise. A standard Manetti is like a Cornish chough, a thing I have never seen. With regard to cutting-back late-budded Roses close to the bud I think "IRIS" is wrong. He should leave about 3 inches above the bud until the spring. If he does not do this the frost will possibly injure the bud.

—WYLD SAVAGE.

### AMERICAN BLACKBERRIES.

HAVING brought these to the notice of our readers, and having some inquiries relative to their culture, we extract the following from "The American Horticulturist":—"The longer Blackberry canes are unpruned the shorter will be the laterals

and the smaller the fruit. To obtain the largest-size berries, and the largest quantity too, cut back the leading canes to not exceeding 4 feet in length, and shorten in also the lateral branches. In July the young wood, which by that time has grown over the tops of the old bearing canes, should be clipped, especially the lateral branches. This will have a very good effect on the following year's crop.

### DIOSPYROS KAKI.

THE generic name affirms that it is a fruit fit for the gods, which is more than the usual exaggeration, for although its bright yellow colour is showy, it is not so good in flavour as a moderate Plum.

The tree is of middling size, and a native of Japan. Mr. G. F. Wilson has obliged us by writing as follows:—

"We bought a few plants of *Diospyros Kaki* at a sale. Two have thriven; one bore fruit this year for the first time. A visitor who had lived long in Japan told me that the fruit was esteemed there, and that if the plant was allowed to carry too much the fruit would almost all fall before ripening. It seems

Fig. 65.—*Diospyros Kaki*.

a prolific bearer; after considerable thinning our small tree in a pot in the orchard house bore eleven fruit. As to the edible qualities of our particular species grown in this country I do not think anyone would wish to taste twice; without being bitter the fruit is intensely astringent. I have seen a number of friends at table twisting their mouths as if they had swallowed a lump of tannin. I should not be surprised if the fruit is found to contain a new valuable astringent principle. A friend to whom I mentioned this, and who has lived long in Australia, said they obtained there an extract from the Gum Tree used as a specific in diarrhoea."

### ROMNEYA COULTERI.

WE have been gratified this week by seeing at Glasnevin the first flowers expand of the singular Californian *Papaveraceous* plant, *Romneya Coulteri*. This is, for several reasons, a very remarkable plant; and for none more so than for its departure from the typical characters of plants belonging to the order *Papaveraceæ*, a near approach to those of *Nymphæacæ* on the one hand, and *Sarraceniaceæ* on the other, thus, as it were, forming a sort of intermediate or connecting link between those three natural orders.

*Romneya Coulteri* is a strong-growing, much-blanching plant, with pinnatifidly lobed glaucous foliage. The flowers are large, nearly equalling in size those of the white Water Lily; colour pure white. Each flower is composed of three sepals and six petals, the latter alternating with each other. The stamens are very numerous; anthers golden yellow. The ovary, which is nearly sessile, is dark-coloured at the base, and internally is divided into several distinct compartments, the ovules, or young seeds, being spread over the entire surface of

the dissepiments. This must, no doubt, be a very showy plant in its own country, as it is apparently very floriferous; but it is doubtful if it will be so valuable in these isles, when the summer heat is not sufficiently powerful for perfecting its growth and fully developing its flowers before our early autumn chills affect it. The plant which has just opened its first flowers in the open border at Glasnevin, and is somewhere about 4 feet high and 3 feet through, with numerous lateral branches, each, as well as the terminal branches, bearing a flower bud at the point, was received by Dr. Moore only last March, and then, we believe, a mere cutting. From this it will be perceived it is a vigorous free grower. The flower that has expanded is the one on the main stem, but it appears to be doubtful, owing to the lateness of the season, if those on the laterals will follow suit. The decorative value of this plant for the mixed border will not be rightly tested until the coming year, when it can be seen if, with the aid of the slight protection which Dr. Moore contemplates, it will be sufficiently hardy to stand our winters, and, with an early start, be able to reach the flowering period while the sun is still powerful. If so, it will be a valuable acquisition.

We have felt constrained to go more into particulars with regard to this plant than we otherwise would by reason of it being so identified with three very distinguished Irishmen. It was first described and the genus founded by the late Dr. Harvey, Professor of Botany in Trinity College, Dublin. The generic name commemorates one of the most gifted of our countrymen—namely, Dr. Romney Robinson of Armagh, whose fame is world-wide; and the specific name that of the late Dr. Coulter, also a professor in our University, and well-known in all the scientific circles of Europe for his botanical attainments, and after whom the leguminous genus *Coulteria* is named. It was he, too, who, during a lengthened residence in Peru, made Cacti a special study, and sent thence to the University Botanic Garden the largest collection of these singular plants ever sent by one man to Europe.—(*Irish Farmers' Gazette*.)

### HARDY ANNUALS.

I ENDORSE what "H. S." says on page 401 respecting hardy annuals for spring flowering, but I think that he is in error when entertaining the idea that our pets are only cared for in large establishments. They are growing in favour, and I expect they will continue to do so. To those "H. S." enumerates I add *Collinsia grandiflora*, for in the spring this lovely flower will vie with any other spring-flowering annual. *C. bicolor* does us good service, too, in bed and border; the plants are in their places now. *Gilia tricolor* stands well through the winter, and flowers early. *Nemophila insignis* is a useful plant for early spring work. *Limnanthes Douglasii* is one of the hardiest of the annuals, and is a fine plant when well grown. *Sphærogyne speciosa* should have a place in all spring gardens. *Linaria bipartita* does us good service as a hardy annual in the spring, but in my estimation *Veronica syriaca* eclipses them all. I set this down as the gem of gems for early spring work, and no kind of weather appears to affect it.

These annuals cannot be had without labour, but it is pleasant labour to prepare for cheerful spring. To grow them well they require sowing the latter end of August. When ready they should be pricked out, and subsequently be moved with balls into their winter quarters as early in October as possible. I find it good practice in very severe weather to stick a few evergreen branches among them, taking away the branches when the severity of the weather is past, and on dry days stirring the surface of the ground among the plants is very beneficial.—A LOVER OF HARDY ANNUALS.

### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**ANTHURIUM BAKERI.**—"The vast genus *Anthurium* contains upwards of 180 species (as enumerated by Schott in his 'Prodromus'), all natives of tropical America, and of which between fifty and sixty were known to that author in a living state, chiefly from specimens grown in the rich collection at the Imperial Palace of Schönbrunn (Vienna), and obtained principally by himself. At Kew, which is also rich in tropical Aroids, nearly one hundred species of this genus are now in cultivation, forming one of the principal ornaments of the Aroid house, where, for number of species, beauty and variety of form of foliage, they dispute the palm with the Philodendrons. They are plants easy of cultivation if supplied with shade,

moisture, and a high temperature, and being remarkably free from insect pests they are well adapted for stove culture.

"A. Bakeri was imported from Costa Rica by Mr. Bull, who presented it to the Royal Gardens, where it flowered first in June, 1872."—(*Bot. Mag.*, t. 6261.)

**MASDEVALLIA IONOCARIS.**—"M. ionocharis is one of the smaller species of the genus, and is remarkable for the bright colouring of the flowers that are abundantly produced in autumn. It was made known by Dr. Reichenbach, who published it from specimens discovered by Mr. Davis in Peru, and flowered by Messrs. Veitch in the Royal Exotic Nurseries, to whom the Royal Gardens are indebted for the specimens here figured, which flowered in September, 1875."—(*Ibid.*, t. 6262.)

**LIBERTIA PANICULATA.**—"A very elegant and free-flowering greenhouse plant, which has been long cultivated at Kew, having been raised from New South Wales seeds. It flowers early in spring. The genus to which it belongs is confined to Australia, New Zealand, and extra-tropical South America, and contains only three or four species; it is thus one of several instances of a close botanical relationship between these distant countries."—(*Ibid.*, t. 6263.)

**FRITILLARIA RECURVA.**—"In colour this is the finest of all the Fritillaries, the red being as bright as that of a Lily, and intermixed, especially in the inside of the flower, with bright yellow. It is a native of California, and belongs to the small group of Fritillaries with Lily-like bulbs. It was first described by Mr. Bentham from specimens gathered in 1848 by Hartweg on the mountains of Sacramento, and has since been collected by Fremont, Jeffrey, and many others. We first received specimens cultivated in Europe from Max Leichtlin, Esq., in 1870. Our stock at Kew was received in 1875 from Mr. Sargent of the Botanic Gardens at Harvard. In England it flowers early in May, or at the latter part of April."—(*Ibid.*, t. 6264.)

**ODONTOGLOSSUM LEVE.**—"One of the earliest introduced species of the genus, having been sent to England from Guatemala by both Mr. Skinner and Hartweg, and having flowered in the Horticultural Society's Gardens early in 1842. O. leve has flowered at Kew repeatedly; for the first time in June, 1864, from plants imported from Guatemala. It is very fragrant."—(*Ibid.*, t. 6265.)

**NECTARINE.**—*Albert Victor.*—"We are indebted to Mr. Coleman, gardener to the Earl Somers, at Eastnor Castle near Ledbury, for the specimen of this remarkably fine Nectarine. No man has shown himself more worthy of being listened to when speaking of fruits and fruit-culture than Mr. Coleman, and that he entertains a very high opinion of this Nectarine, the following note, which he has kindly communicated to accompany the figure, will show:—

"This fine variety, raised by Mr. Rivers, is well worthy of general cultivation. I have fruited it four years, and find it is a good grower, a free setter, and swells its fruit to a large size. In point of ripening, it comes in a few days later than Elruge, and hangs a long time after it is ripe, when the flavour, always good, becomes delicious. Planted out and trained under glass or against a wall, I am of opinion that this will become one of the finest Nectarines in cultivation, fit for the choicest dessert, and indispensable to the exhibitor.—W. C."

"This grand variety appears to have been raised by Mr. Rivers from the Prince of Wales Nectarine, and is a large and handsome fruit, belonging to the group with small flowers and round glands."—(*Flor. and Pom.*, 3 s., ix., 241.)

### NOTES AND GLEANINGS.

At the annual meeting of the members of the DARLINGTON GARDENERS' INSTITUTE the Secretary read the following report, which was adopted:—In presenting the third annual report of the Gardeners' Institute, the Committee congratulate the subscribers on a satisfactory increase in their number, and also in their income, though owing to the expenses incurred in the removal of the Institute to more convenient premises they are unable to report any balance in hand. They are glad, however, to report that the subscriptions have fully covered expenses. Papers have been read by the following gentlemen:—Mr. Richardson, "What to Read and How to Read it;" Mr. Wrather, "The Cultivation of the Rose;" Mr. Wand, "Tricolor Geraniums;" Mr. Casson, "Fumigation;" Mr. Shaw, "The Strawberry;" Mr. Burrell, "The Gladioli;" Rev. C. King, "The Leaf—botanically, &c.;" Mr. Helier, "Stage Pelargoniums;" Mr. Casson, "The Flow of the Sap." The Committee are glad to report that those readings have

been numerously attended and much appreciated, and the cordial thanks of the Institute are due to the gentlemen named for their kindness, and they express a hope that those readings may continue. They also report and gratefully acknowledge the gift of a valuable microscope from Mr. J. W. Pease, M.P. Twenty-one meetings for the inspection and naming of fruits and flowers have been held, and those meetings have been useful, interesting, and instructive. A sub-committee have during the summer season held several open-air concerts, through the kind permission of the owners, in the grounds of West Lodge, Polam, and Woodlands. The balance sheet showed the receipts and expenditure amounted to £61 6s. 11d.

THE Crystal Palace Company are announcing as a prominent attraction their collection of CHRYSANTHEMUMS now arranged in the central transept. The display is an excellent one, and is deservedly admired by large numbers of visitors. The plants are arranged in front of the orchestra, and occupy a space of 50 yards in length by 4 to 6 feet in breadth. They vary from 3 to 8 feet in height, and are composed of the best of the large-flowering and Pompon varieties. They are in excellent health, having good foliage and many "exhibition" blooms. Especially fine are White Globe, Empress of India, Aurea Multiflora, Dr. Sharpe, Golden Beverley, Mrs. G. Rundle, Pink Perfection, Prince of Anemones, Jardin des Plantes; and attractive by their rich colours are Cardinal Wiseman, Oliver Cromwell, and Progne. The most noteworthy of the Pompons is Model of Perfection. The exhibition will continue for some time longer, Mr. Thompson having hundreds of plants in reserve in one of the corridors. It is the best display of its kind that has been seen in the building.

— We have recently seen with what good reason Mr. Luckhurst occasionally refers to the profitable nature of ESPALIER FRUIT TREES. His father has for a term of about forty years been gardener at The Mote, near Maidstone, the estate of Lord Romney, but now in the occupation of Lady Howard de Walden. The trees which Mr. Luckhurst, sen., planted in that garden thirty years ago are now remarkable "hedges," fringing the walks of the fine kitchen garden, and even during the present season the crops of fruit produced by these trees have been very good. The espaliers are about 5 feet high and are nearly "self-supporting"—that is, only a stake here and there is required to support the branches. They are not formally trained horizontal cordons, but in reality are hedges of Apple trees bristling with spurs and producing annually superior fruit—such crops as no other system of culture could produce on the same limited space, and with the same small outlay in labour which is necessary to keep the trees in order.

— UNDER the able superintendence of Mr. F. Bause, MR. WILLIS'S NURSERY at ANERLEY resembles the Belgian plant manufactures. By rapid propagation Mr. Bause has crowded the several houses with new and valuable plants, the *Dracænas* alone numbering about ten thousand. Another extensive batch of seedlings has just been pricked out in a hundred pans each containing about a hundred plants. The beautiful *Yucca filamentosa variegata* continues to be increased in the same successful manner that has been previously noticed. Ferns are raised from spores apparently as freely as are Mustard and Cress from seeds. Pitcher-plants are numerous and fine. Anthuriums, not only *A. Scherzerianum* but *A. crystallinum*, are growing from seeds like Radishes, and *Lapagerias* are being struck from cuttings in large batches. Altogether the nursery is in capital order, and possesses many features of interest to propagators and those identified with the increase and cultivation of new and popular plants.

— AN American writer informs us that WRAPPING THE STEMS OF TREES for an inch or two below the ground to a foot or two above with coarse brown paper, bass bark, or old sacks of any kind, after which smearing the outside with coal tar, will prevent the depredations of rabbits, mice, and similar vermin.

— A PLANT of the greatest value for winter decoration is *LASIANDRA MACRANTHA FLOREBUNDA*. It is a dwarf form of *L. macrantha*, and was found in Brazil by the late Dr. Seeman. The great usefulness of this plant is, that it produces its splendid violet-blue flowers in profusion when in quite a small state—that is, cuttings struck in the spring form plants which flower freely during the following winter. We have recently noticed plants about 6 inches high and growing in 5-inch pots, each plant showing six to twelve flowers. These plants were grown in frames during the summer, and will shortly be worthy of being associated with dwarf Poinsettias, and

it will not be easy to determine which are the most effective, the brilliant scarlet bracts of the one, or the large rich violet flowers of the other. This dwarf *Lasiandra* is recommended as meriting extensive cultivation.

— ONE of the sweetest of Orchids is *BURLINGTONIA FRAGRANS*; its perfume may be described as that of May blossom intensified. This plant was recently flowering—indeed, it appears to be almost always in flower—in the collection of Mr. Bull at Chelsea. The plant is growing on a block, and its pendulous racemes of delicate bluish-tinted flowers are very attractive. It is a most enjoyable Orchid, and worthy of a place in all collections of stove plants.

— WE are informed that the ROYAL HORTICULTURAL SOCIETY OF IRELAND'S winter Show, which was held on the 9th inst., was an excellent one. The principal feature was the Grapes exhibited by Mr. Roberts, gardener to the Countess of Charleville. The variety was *Gros Guillaume*, three bunches weighed in the aggregate 45 lbs. The weight of the largest bunch was over 16 lbs., the other two weighing 15 lbs. and 14 lbs. respectively. Each bunch was well finished, and they were altogether most praiseworthy examples of cultural skill.

— ALTHOUGH the system of growing WATERCRESSES in POTS has been frequently mentioned, that mode of culture is not by any means generally adopted. Yet nothing can be more easy of being carried out, and a supply of sweet and quickly grown "Cresses" may be had throughout the winter by all who will pot a few plants and place them in any heated structure. The roots should be placed closely together in 6-inch pots, using rich soil and potting lightly. The pots should then be placed in deep saucers of water on a shelf in any moderately heated structure. We have lately seen some productive pots of Watercresses at Munster House, Fulham, and Mr. Pithers the gardener, spoke in high terms of the simplicity and usefulness of this mode of culture.

— WE have to-day (November 14th) seen a further supply of STRAWBERRIES from Rabley. The fruit was perfectly ripe, medium-sized, and well coloured. The plants producing this fruit were forced last year, and afterwards planted in the open ground: on showing trusses in the autumn the plants were again potted, and two hundred of them are now in full bearing, and very valuable.

— WE omitted to notice in our report of the last meeting of the Fruit and Floral Committees that a gold medal was recommended to be given to Mr. Ollerhead for Orchids, and a similar award to Mr. Ross, Welford Park, Newbury, for four Smooth-leaved Cayenne Pine Apples weighing respectively 7 lbs. 4½ ozs., 8 lbs. 5 ozs., 9 lbs. 2½ ozs., and 10 lbs. 5½ ozs. The suckers which produced these fruits were potted in 6-inch pots in June, 1875, and shifted into 11-inch pots in April, 1876.

— MR. JUDD, late of Oxtou Hall Gardens, has been appointed gardener to the Earl of Warwick, Warwick Castle. Mr. Phipps, late of Ingestrie Hall, succeeds Mr. Scammell at Bowood; and Mr. Edwards, late Superintendent at the Regent's Park, is succeeded by Mr. Brown from Hampton Court.

— MR. G. DAWSON, after alluding in the *Irish Farmers' Gazette* to the annoyance caused by SLUGS in nibbling Mushrooms when in a small state, writes, that "about 2 inches thick of the roughest sawdust to be had, put all over the beds, proved the best protective we ever tried both against woodlice and slugs. Neither of them likes to travel over dry sawdust. And Mushrooms before fit for use, are sure to push up quite enough through the sawdust to let a person know where they are; indeed, they generally throw themselves right above the sawdust before they are of the size of a crown-piece. Should the beds require to be watered, it is best to clean the sawdust completely off, then water according to need; let the surface dry as much as possible before returning the covering, as the sawdust, to do good service, cannot be overdry."

— THERE was again a very full attendance of members at the usual monthly dinner of the HORTICULTURAL CLUB at their clubhouse, 3, Adelphi Terrace, on the 8th inst. The Hon. and Rev. L. T. Boscawen presided. Much interesting discussion took place after dinner, especially in reference to the Royal Horticultural Society and Mr. G. F. Wilson's efforts for its revival. Mr. W. Wood of Maresfield and Mr. Andrew Henderson of Pine Apple Place were elected members. The next dinner (which will be the anniversary) will be on December 6th.

— MR. ABBEY sends the following corrected mode of compounding the INSECTICIDE which he recommended on page 401

as being fatal to insect life, and a valuable dressing for fruit trees:—"Take of soft soap half a pound, to which add a wine-glassful of spirits of turpentine, mixing thoroughly with the soft soap, forming a paste. Have ready boiling tobacco juice and add a little at a time, and stirring so as to incorporate the whole. If the whole of the tobacco juice can be added without the soft soap and spirits of turpentine being made to clot or curdle it will not afterwards become separated, and is ready for use at any temperature below 120°. If, on the other hand, the tobacco juice causes the soft soap to be separated or refuses to combine with the tobacco juice, clotting taking place, only add tobacco juice so as to render the separation complete. In some cases the soft soap and spirits of turpentine will not combine with more than a quart or less of tobacco juice. When the clotting takes place we have the quantity of tobacco juice required, and we make up the quantity short of half a gallon with boiling water, thereby effecting a thorough combination of the ingredients."

— We are informed that at the GLOUCESTERSHIRE ROOT, FRUIT, AND GRAIN SOCIETY'S SHOW there was an unexpectedly good collection of roots of excellent quality; the fruit was fine, if not so specially remarkable as at some previous exhibitions. A small though exceedingly good collection of Grapes was sent by Earl Ducie and Mr. Gambier Parry; and the place was made bright and cheerful by groups of Chrysanthemums and baskets of flowers and ornamental plants. The class for twelve of Wheeler's Golden Melon Mangolds, for which special prizes of ten guineas were given, deservedly attracted much attention. All the specimens exhibited were large, heavy, clean, and well-shaped.

— An American writes as follows on DISSOLVING BONES:—"I have a large water-tight hoghead standing outdoors near the kitchen. In the spring I cover the bottom about 6 inches deep with dry soil. On this I put a layer of bones of about the same depth, and cover them entirely with unleached ashes. On these another layer of bones, then ashes, and so on till the hoghead is full. I leave it then exposed to the rains all summer and winter until the next spring. Then, on removing the contents of the hoghead, I find nearly all the bones so soft that they will crumble to powder under a very slight pressure, and, mixed with the ashes and the soil, they give me a small pile of most valuable manure ready for immediate use. Any of the bones not sufficiently subdued I return to the hoghead again for another twelve months' slumber. In this way I have had no difficulty in transforming all the bones I can get into bone meal. I buy them directly from the butcher for the purpose of turning them thus into manure, and consider them the cheapest fertiliser I can obtain."

— THE CAROUBA TREE of Brazil appears to be a vegetable of some value, and, if the half that is told of it is true it should be cultivated wherever it can be made to thrive. It is a species of Palm, and flourishes without culture at Bahia, Rio Grand do Norte, and other well-known localities, resists drought, and always appears green and luxuriant. Its roots possess properties similar to those of the Sarsaparilla. The trunk furnishes a superior fibre. When the tree is young it yields wine, vinegar, a saccharine matter, and a species of gum closely resembling sago. Its wood is excellently suited for the manufacture of musical instruments, as well as for tubes and conduits for water. The pulp of the fruit is very palatable, and the oily nut roasted and pulverised is a good substitute for coffee. The trunk also yields a flour similar to maizena. With the straw, hats, brooms, and baskets are made, and over half a million dollars' worth of it is exported to England yearly. Lastly, a wax used in the manufacture of candles is extracted from the leaves.

— THE late Mr. EDWARD GEORGE HENDERSON, whose death was announced in our last issue, was the eldest son of Andrew Henderson, the founder of the Pine-Apple Nursery. Mr. E. G. Henderson at the beginning of the present century commenced business on his own account at the nurseries in Edgware Road, known as Vine Place. In those days fruit-growing not being nearly so extensively carried out in private places as at the present time, both Pine-Apple Place and Vine Place Nurseries were, in addition to the culture of popular plants, greatly devoted to the culture of fruit, which was supplied in large quantities to the nobility and gentry in and around London; but it was a well-known fact that the Pine-Apple Nursery produced the best Grapes and the Vine Place Nursery the best Pine Apples. About forty years ago he left the Vine Place Nursery and removed to the Wellington Road, at which esta-

blishment he continued to cultivate an extensive and varied collection of plants until about twelve years ago, when he retired from taking an active part in the business.

— We regret to announce that Mr. THOMAS PATERSON died on the 12th inst. at the Royal Horticultural Gardens, Chiswick. He was forty-two years of age.

— NOTWITHSTANDING all researches and efforts, says the *Annales Industrielles*, the terrible insect PHYLLOXERA continues and extends its ravages daily. All our Vines are now menaced with an invasion by it. Ascending by the valley of the Rhone, it is now on the point of reaching our large vineyards of Burgundy; and in the west, having invaded the whole valley of La Garonne, Le Bordelais, Les Charentes, it has suddenly made its appearance even in the Loiret, in the heart of the magnificent nurseries which are the fortune of the environs of Orleans. It is not (this writer continues) that we have not numerous means for destroying it, and we have no fear for the vineyards that produce the better Vines of France; their value is sufficient to meet the expense of suitable treatment. What we are far from possessing yet is a treatment economical enough to be applied to the Vines of less value, which produce only *vins ordinaires*. Thus the sulphide of carbon and alkaline sulpho-carbonates, now largely used, succeed perfectly; but these substances are still too high in price, and their application involves expense for manual labour, which can only be supported by vineyards whose yield is of high value.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

We have sowed Peas on a border facing south. The ground was very dry, and the drills were drawn in the usual way. The Peas were wetted with a carbolic solution, which is said not only prevents the attacks of mice but also of sparrows when the plants come through the ground. If this is so it will be a great boon to us, as sparrows are a much greater pest than mice. In wet soils some growers recommend sowing the seed on the surface of the ground and drawing the soil over them to the depth of about 3 inches. Others draw the soil up into ridges about a foot high, and sow on the top of the ridges; but this last plan can only be recommended when the district is very wet indeed. Beans may also be planted now for the earliest crop.

After clearing away the stalks and outer decaying leaves from Artichokes, the surface of the ground should be covered with stable litter to the depth of 9 inches or a foot. This is a very good protector from frost, or the same material may be used mixed with an equal quantity of decaying leaves. We have never used spent tan after it is no longer useful for producing bottom heat in tan beds, but have heard that it is well adapted for protecting the plants from frost. All the late Celery ought now to be secured from frosts by earthing it up in fine weather. A covering of littersy manure may be placed over the soil to keep frost out of it.

Admit air to Cauliflower plants in hand-glasses and frames, only letting the lights remain on during very severe frost. The lights may be tilted as much as possible in wet weather, but the plants must not be exposed to the rain. Those who have not yet pricked-out their plants should do so as soon as possible. All decaying leaves should be removed from recently-put-out plants, and the soil be lightly forked over between the rows, and all weeds removed.

We have removed the old leaves from Seakale plants which are intended to be forced, and should the plants not be taken up and potted, which is our usual method, the ground will be covered over with rough manure, so that the plants may be easily dug-up should severe frost set in. It is a good plan to cover-up the crowns of all old plants either with ashes or manure preparatory to covering the beds a foot or 15 inches thick with leaves.

The treatment recommended for Celery is applicable to Cardoons, which must be finally earthed-up and protected from frost. Some good growers of Cardoons recommend that they be not earthed-up at all, but that some straw be placed in an upright position against the plants, and be kept in its place with hay or straw bands.

It is quite necessary that all winter-growing crops be kept free from weeds. The weather has lately been excellent for allowing the Dutch hoe to be worked amongst rows of Onions, Lettuce, Cabbages, &c. Lettuce plants in frames or anywhere under glass require plenty of air. In fine weather the lights must be entirely removed, and be tilted in wet weather. In frosty nights the frames must be kept close. Remove all decaying leaves, and loosen the soil between the plants.

Let the kitchen garden be kept neat and free from all decaying

vegetable matter. The stalks of Cabbages, Broccoli, Cauliflower, &c., should be carried to the vegetable refuse heap. All vacant ground should be dug or trenched as quickly as possible, so that it may be ready for the beneficial influences of winter frosts.

#### VINERIES.

We have but little to record of our own doings this week. All the early houses are ready for forcing, and where there are no plants the lights and front sashes are open night and day. There is considerable advantage in having vineries either early or late devoted to the Vines and nothing besides. There is no apparent harm, perhaps, in having the houses closed at night and the frost merely kept out, but even if there were no other evil it must be better to allow a free circulation of air on all occasions. Much injury is, however, likely to result both from watering the plants and keeping out frost. The ground beneath plants requiring much water becomes a puddle when it ought to be comparatively dry; then, in keeping out the frost, the temperature is often raised as much as 10° higher than is necessary, 45° being registered when 35° is better for the plants and would do no injury to the Vines. In our houses, where it is necessary to place plants over the borders, saucers are placed under the pots to hold superfluous water, but the pots must on no account stand in the water. The best plan is to invert a pot underneath that containing the plant. The saucers are emptied when they become full.

Late vineries where fruit is hanging must be ventilated as freely as possible, and artificial heat should be applied to keep up the temperature to 40° at night. If frost should gain admittance the Grapes will damp off rapidly.

Questions are frequently asked in reference to the formation of Vine borders. Much has been written and published in the pages of this Journal on that subject. Elaborate composts have been recommended, as well as instructions given on excavating, concreting, draining, &c., and many amateurs fancy that without all this trouble good Grapes cannot be obtained. Now, when good turfy loam can be procured in abundance and money is no object, let a good border be made by all means; but when loam has to be purchased at a guinea a ton, as is the case about London, it is but few that will use it for Vine borders. Good garden soil enriched with decayed manure and crushed bones will grow Vines well, and Grapes will be produced whenever the wood is strong and well ripened. Good drainage is necessary, as Grape Vines will not do well in soil where water is stagnant. The present is a good time to make Vine borders, and they ought to be left exposed to the winter's frosts, the Vines to be planted in March.

*Strawberries for Forcing.*—Ours are yet exposed in the open ground, as it is not convenient to store them in the orchard house until it is partly cleared of Chrysanthemums. We used to store them in frames at considerable inconvenience until the house was ready early in December, but we have found that the plants remain in a more healthy condition if left out of doors. They suffer nothing from frost, and if too much rain falls it is easy to lay the plants on their sides. The leaves hang over the sides of the pots and throw off much rain as well as protect the roots from frosts. We shall place the first lot of Black Prince in the earliest vinery to start them about the end of the month. Sometimes it is not convenient to place the pots in the vinery, and it is not well to move them from a cool house to the temperature of a Pine house all at once. We have in such a case made up a hotbed and plunged the pots in a gentle bottom heat to excite root-action.

#### PLANT STOVE AND ORCHID HOUSES.

It is now a good time to see that all plants are thoroughly cleansed from scale, mealy bug, thrips, &c. Our time has been occupied with such work during the last week or two. At this season everything ought to be kept clean and neat in all the houses, and flowering and foliage plants be arranged to the best advantage. As all the winter-flowering species and varieties of Calanthe lose their leaves while they are in flower, the best arrangement is to place the plants amongst the green leafage of Ferns. The pretty little Indian Crocuses (Pleione) has also a charming effect at present, but it also is bare of leaves. Its flowers open before the leaves appear. A charming plant at present in the warm house is an autumn-flowering variety of *Dendrobium formosum*. This fine *Dendrobe* may be classed amongst the "bridal" Orchids; its pure white flowers with a pale yellow lip are very effective for bridal bouquets. The plant is not often grown well, yet it is of easy culture. It will not thrive in a pot, nor well in a basket if too much peat or sphagnum is placed in contact with roots. Our plants have made strong healthy pseudobulbs with nothing but potsherds in the baskets. We hang the baskets up near the glass in a temperature of 65° at night, and the roots make vigorous growth all round the woodwork. *Lælia anceps* and varieties of it are handsome Orchids for flowering in winter. The variety *Barkerii* is much finer than the species, and *Dawsonii* is not only very beautiful, but it is not easily obtained. We have seen a plant of it sold at Stevens's rooms with only two leading growths for

£42. The plants are now throwing up their flower spikes, and it is necessary to watch at night to see that no straggling slug cuts the stalks in two. All Orchids require careful attention during the winter season; although most of them are at rest, it will not do to neglect them. Deciduous plants may be kept without water during most of the winter, but all the evergreen species must have sufficient moisture to prevent the pseudobulbs from shrivelling.

#### FLOWER GARDEN.

The recent cold weather has quite destroyed all the summer-flowering plants, and they have been carted out to the rubbish heap. The beds have been cleared from weeds by raking the ground over. The old beds of *Phloxes* which have been planted two years have been destroyed, and young plants will be put in their places when the ground has been trenched deeply and well manured. The *Phlox* delights in rich soil, and young plants should not be planted on the same ground where old plants have been previously if it can be avoided. Herbaceous borders require to be hoed or lightly forked over if the plants are not too closely together. Some enthusiasts say, "Do not disturb your herbaceous border in the autumn, and allow all the leaves that fall from the trees to remain on it." This is, we fancy, a slipshod style of gardening. It is evident that a covering of dry leaves would be useful to protect any tender plants from frost, but it is doubtful if they would fall or be blown on the right spot. They would rather gather round the crown of some very hardy plant, and the small or more exposed tender subjects might be open to the biting blast. Mr. Matthews of Weston-super-Mare, exhibited some bottomless seed-pans at South Kensington last week, which would just answer the purpose of protecting choice and tender plants. By placing one of those over the plant and a square of glass over the pan the object would be attained. The glass would admit light while it defied the entrance of wet, and frost would be kept out to a certain extent. Failing these some cocoa-nut fibre refuse would keep off much frost.

Auriculas require to be looked over weekly to destroy green fly and have all dead or decaying leaves removed.—J. DOUGLAS

#### TRADE CATALOGUES RECEIVED.

Kelway & Son, The Royal Nurseries, Langport, Somerset.—*Catalogue of Gladioli.*

John Harrison, Leicester.—*Catalogue of Select Roses and Fruit Trees.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

BRIXTON HILL (Chrysanthemums). November 17th and 18th. Mr. G. Goldfinch, Sec.

LOUGHBOROUGH (Chrysanthemums and Fruit). November 21st. Mr. John West, Chapman Street, Loughborough, Sec.

BIRMINGHAM. November 22nd and 23rd. Mr. J. Hughes, Monument Place, Parker Street, Edgbaston, Sec.

LEEDS. November 24th and 25th. Mr. George Hemming, Hon. Sec.

ISLE OF THANET. August 30th, 1877. Mr. C. D. Smith, Hon. Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

BOOKS (J. C. W.).—We have no "Stove Manual," but our "Indoor Gardening" (1s. 6d.) and "Heating Manual" (6d.) include stove management.

BATTY LANGLEY.—The Editors wish to purchase, or would be obliged by the loan of, the engraved portrait of this writer on architecture and gardening. They require it to be copied by their wood engraver.

GARDENERS' TRAVELLING EXPENSES (V. S. P.).—The rule is that the employer pays the travelling expenses of a gardener coming to a new situation. The employer does not pay the expenses of moving the gardener's wife and family unless he has specially agreed to do so.

LEMON TREE UNHEALTHY (H. F. G.).—We cannot make out what the "blight in the shape of a scab" may be. Probably the tree is infested with scale, which may be removed with a sponge, employing soft soap 8 czs. to half a gallon of water, adding a wine-glassful of spirits of turpentine, syringing the plants with clear tepid water immediately after being freed of the filth, taking care that the solution does not pass down the stem to the roots. If the "scab" be upon the stem of the plant, it will in all probability die. Send us a specimen twig.

CHRYSANTHEMUM SHOW.—"An Amateur" wishes to know if a Chrysanthemum Show is held near Finsbury Park.

CARICA PAPAYA (T. E. D.).—The specimen sent is correct. There is a portrait of the tree in the "Botanical Register," t. 459. The white mites do not injure it; they feed on the decayed part. Your plants die probably because the temperatures are too low, and have too much water. They

require light soil, little water, a high temperature, moist air, and roots undisturbed.

**PROPAGATING MESEMBRYANTHEMUMS (A Reader).**—Cuttings should be inserted early in March, in a compost of equal parts of turfy loam, sandy peat, and silver sand, draining the pot or pan well, and surfacing the compost with half an inch of silver sand, watering before insertion, and putting in the cuttings six hours afterwards. In a gentle hotbed they will strike freely. Seedlings may be raised by seed sown at the same time, omitting the surfacing with sand, and just or barely covering the seed.

**RAISING MYOSOTIS FROM SEED (Idem).**—Sow the seed next April or early in May in the open ground, pricking off the plants when large enough to handle, and removing them to their flowering quarters in autumn.

**GERANIUM POTS COVERED WITH MOULD (Idem).**—It most likely arises from the soil being too wet and sour. Remove the mould with a stick, loosening the surface of the soil.

**PLANTING ALSTROEMERIAS (A. F. B.).**—Plant the roots now 8 inches deep in good rich soil in an open situation but sheltered, surrounding the roots with a little sand. Pot the bulbs of *Brodiaea grandiflora* at once in fibrous loam, leaf soil, and sandy peat in equal parts, covering them about an inch deep, and keep in a cold pit but protected from frost until roots are plentifully formed, after which remove to the greenhouse or window, or you may plant the bulbs 4 inches deep in a warm border. *Trichonema speciosa* requires to be treated the same as *Brodiaea*.

**EARLY SPRING FLOWERS (C. T., Sussex).**—There are many other good spring bedders besides those you mention. Here are some of them, with heights, colours, and time of coming into flower: *Gentiana verna*, blue, 4 inches, April; *Gentiana acaulis*, deep blue, 6 inches, April; *Hepatica triloba*, 6 inches, February, single and double pink, the same of red, mauve, and blue, and single white; *Iberis corifolia*, 9 inches, white, March; *Delytra spectabilis*, 2 feet, deep pink, April; *Cheiranthus Marshallii*, 9 inches, rich yellow, April; *Aubrietia deltoidea*, 6 inches, lilac, April; *Aubrietia Campbellii*, 6 inches, purple, April; *Arabis albidia*, 9 inches, white, February; *Alyssum saxatile*, 9 inches, yellow, April; *Nemophila insignis*, 9 inches, light blue, April; *Saponaria calabrica*, 9 inches, pink, April; *S. calabrica alba*, white, uniform in height with the pink sort, and flowering at the same time.

**RAISING YOUNG TULIP TREES (Idem).**—Tulip trees are propagated in this country by seed imported from America. It is only in favourable seasons like the present that the seed ripens with us. Sow your seed immediately in pots placed in a cold frame, let the young seedlings remain in pots, plunged in an open border the first year, in order to check their excessive tendency to form tap roots.

**CAMELLIAS WITH FOUL FOLIAGE (L. Shaw).**—Examine the stems and branches closely and you will probably find them infested with scale, the excrement of which being the "filmy black sticky substance" that you are so much troubled with. The inspection must be close, and the cleansing thorough. Do not, however, rest satisfied with a single washing, but repeat it in a week or two, and you will have little subsequent trouble.

**BLACK HEART CHERRIES NOT SETTING (G. G.).**—Cherry blossoms are very susceptible to injury from frosts. You do not say whether your tree is a standard, or whether it is in the open ground or against a wall. In Essex we have Governor Wood and May Duke bearing good crops annually, while we were obliged to grub a number of other good sorts out, including Duchesse de Fallan and Empress Eugénie. You cannot do more to your tree than you have done. Grub it out and plant Governor Wood, which is a fine-flavoured free-bearing sort.

**RAISING STRAWBERRY PLANTS FROM SEED (R. D.).**—We sow our seeds as soon as the fruit is ripe, and place the pots in a cold frame. Some of the seeds vegetate at once, but the largest number of plants do not appear until the following spring, and they form strong plants and produce a crop of fruit the following season. You had better sow your seeds on a gentle hot-bed in March. The Alpines would bear fruit late the same season. They require the same treatment as the other varieties.

**BEDDING GERANIUMS NOT FLOWERING (Idem).**—It is singular that your Zonals do not flower freely, as the treatment you give them is right. What sorts do you grow? Corsair, Wellington, Ianthé, Christine, Mrs. Haliburton, Amaranth, and many others flower freely with us in richer soil than yours. We insert our cuttings about the end of August. If you keep your *Verbenas* free from red spider, green fly, &c., and supply the plants with water during drought they will grow and flower well.

**GLAZING VINERY AND MAKING VINE BORDER (D. P. B.).**—We do not know of any vineries glazed with the roof glass butted. We think you would be able to grow good Grapes by mixing a quantity of turfy loam and crushed bones with your rich garden soil. It is necessary to see that the border is effectually drained.

**GRAPES IN EARLY AND LATE VINERIES (J. A.).**—We do not think Lady Downe's Seedling would be a good stock for an early White Grape. As you already have Dr. Hogg, it would be as well to train a rod of that sort up, and replace Lady Downe's with it; or if you want a Sweetwater, inarch Buckland Sweetwater on one of the Hamburgh rods. Royal Muscadine will bear freely enough if you train up a young rod, and the stronger the wood it makes the more freely it will bear. We cannot advise you to plant another variety for a conservatory.

**HEATING BY PETROLEUM OIL.—"W. L. O."** wishes to know the expense of heating a greenhouse 20 feet by 12 feet by burning this oil in a stove.

**ROSE PLANTING (Alpha).**—The Rose trees now planted do not require watering. Cocoa-nut fibre refuse 2 inches deep will exclude severe frost from the roots.

**WHITE ISCHIA FIG.—"A very old Reader of the Journal"** will be obliged by "K." saying how his trees are trained, and for full information how best to grow Figs for market. In our "Fruit Gardening Manual," price 4d., full directions are given for cultivating the Fig.

**PLANTING RHODODENDRON (South Devon).**—In answer to your query—"Do cattle crop, or rabbits and hares eat, Rhododendrons?" Our reply is that we have thousands of Rhododendrons in variety disposed in groups over about 15 acres of pleasure ground, the Rhododendrons having shoots within reach of horses, cows, and sheep, and hares and rabbits are very numerous, especially the latter, and have free access to the evergreens, yet none of those quadrupeds interfere with the growth of the Rhododendrons. We, however, question the propriety of placing the Rhododendron within the reach of domesticated animals, as a casual partaking thereof may lead to disastrous consequences on account of the narcotic properties of this shrub. We shall

prune ours so as to place them beyond the reach of cattle. Everyone wishing for evergreen growth should plant Rhododendrons. The common varieties are now as cheap as Laurels, and their growth, though not so free, is more dense, having an additional advantage in flowers. They grow in any soil, except sand and limestone, devoid of vegetable matter.

**"BLIND" PRIMULAS (Amateur).**—The trusses you sent us are anything but devoid of flowers; some, indeed, had flowers opened when the box reached us, and those were perfect in style, stigma, and ovary; the opened calyx of the others had perfect pips, and would in due time have developed. The footstalks of the trusses are very weak, and the flowers are the worst we have ever seen. It is usual for the flowers to expand successively, which may have led to your concluding the trusses were blind. Weak liquid manure would improve the size of the flowers, assigning the plants a light airy position near the glass. Your plants are from a poor strain, not worth culture. On comparing the flowers of yours with ours, we find yours are not much over half an inch across, ours averaging 2 inches in diameter.

**ERROR.**—On p. 408, column 2, and line 25 from top, for "two" read "too."

**NAMES OF FRUIT (R. E. Horsfall).**—1, Comte de Flandre; 3, Susette de Bavy; 4, Beurré Diel; 6, Thompson's; 9, Van Mons Leon le Clerc; 10, Triomphe de Jodoigne. (E. H. R.).—The tall Apple is Cathead, and the round one Striped Beehing. (M. C. D.).—*Crataegus tanaecifolia*.

**NAMES OF PLANTS (J. Dukes).**—We cannot name from leaves only.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### THE CRYSTAL PALACE SHOW OF POULTRY, &c.

WE wonder what the owners of the four thousand pens of birds thought when they were packing-up on Monday morning to consign them to the Sydenham meeting. No doubt many expected prizes who have not had a card, and very probably the less sanguine have had their share of success, for in the Palace lottery, sad to say, there are so few prizes in comparison to the blanks. But it is always well before these great meetings to demolish all one's airy castles, for it is often hard to have to do it afterwards. Many must be disappointed, for new birds make their *début* here, and old favourites have to be put upon the shelf, perhaps only temporarily, until, having rested, they are once more fit for battle, like

"Suns that set and moons that wane,  
Rise and are restored again."

As the Show is this year one day later in the week we cannot give our annual report until next week. Suffice it to say now that the quality is as good as ever, and the number of perfect specimens in the various breeds very large. Some names are missing from the catalogues—old household names in that body of exhibitors—some of them because the ranks have been thinned by death, and some of them from declining the fancy. Of the former we miss two very much, for we had for years been in the habit of going over the French and Cochon classes with them.

In other respects the Palace Show of 1876 much resembles the Palace Show of other years, for we see Mr. Billett walking about among his pens as usual. We see the same managing Committee rosetted and courteous. We recognise nearly the same faces, and in many cases the same birds. We can almost imagine we have slept for a twelvemonth and have woke-up and found the Crystal Palace Show where we left it in 1875. In appliances there is the same show houses, polished and varnished like drawing-room furniture; incubators, too, hatching, when they will never hatch at home; stalls of medicated compounds, and spices in tins and canisters, poultry baskets, poultry books, poultry papers—in fact all that is wanted at the Palace Show to make one become a poultry fancier is a "pocket full of rye," and from the number of "sold" cards about, in spite of the money market, trade stagnation, rumours of wars, and many such disturbances, we can fully believe that there are yet left many who can, king-like in the nursery rhyme, go into their counting-house and count out their money.

Thus much, then, for preface; the stern reality of criticism will come next week, and in the meantime we give our readers the prize list of this gigantic Show.—W.

#### POULTRY.

**DORKINGS.**—Coloured.—Cock.—1, Mrs. Arkwright. 2, G. Ellis. 3, H. Verey. Hen.—1 and Cup, F. Parlett. 2, F. Parlett. 3, T. C. Burnell. Cockerel.—1, Cup, and 4, O. E. Cresswell. 2 and 3, T. C. Burnell. 5, F. Caws. Pullet.—1 and Cup, E. Ponting. 2, Dr. Snell. 3, H. Brown. 4, H. Kilsey. 5, P. Ogilvie. Silver-Gray.—Cock.—1, Miss Easley. 2, W. W. Rutledge. 3, O. E. Cresswell. Hen.—1, Cup, and 2, P. G. Burnell. 2, O. E. Cresswell. Cockerel.—1, Cup, and 2, T. C. Burnell. 3, O. E. Cresswell. Pullet.—1, O. E. Cresswell. 2, T. C. Burnell. 3, Countess of Dartmouth. Blue or Cuckoo.—1 and 2, T. C. Burnell. 2, H. H. Young. White.—Cock.—1, Mrs. Hayne. 2, O. E. Cresswell. 3, R. A. Boissier. Hen.—1, Cup, and 2, O. E. Cresswell. 3, W. Clementson. Any variety.—1, Lord Tarnour. 2, P. Ogilvie. 3 and 4, F. Caws.

**COCHONS.**—Cinnamon or Buff.—Cock.—1 and Cup, G. H. Procter. 2, Mrs. Christy. 3, Lady Gwydyr. Hen.—1, G. H. Procter. 2, Mrs. J. Davidson. 3, A. Darby. Cockerel.—1 and Cup, Mrs. A. Tindal. 2 and 3, W. A. Burnell. 4, R. P. Percival. Pullet.—1, R. P. Percival. 2, H. Tomlinson. 3, A. J. E. Swindell. 4, W. A. Burnell. *vhc.* Lady Gwydyr. Partridge.—Cock.—1 and Cup, H. Tomlinson. 2, T. Stretch. 3, Lady Gwydyr. *vhc.* E. Tudman. Hen.—1, Mrs. A. Tindal. 2, E. Tudman. 3, J. N. C. Pope. *vhc.* R. P. Percival. Cockerel.—1, W. A. Burnell. 2 and 3, E. Tudman. *vhc.* Mrs. Gordon. Pullet.—1, C. Sidgwick. 2, E. Tudman. 3, Mrs. A. Tindal. *vhc.* A. W. Burnell. *vhc.* E. Tudman. White.—Cock.—1, Cup, and 2, R. A. Boissier. 3, R. P. Percival. Hen.—1, Mrs. A. Tindal. 2, G. H. Procter. 3, R. A. Boissier. Cockerel.—1, Mrs. A. Tindal. 2, R. A. Boissier. 3, Rev. H. J. Bortow. Pullet.—1 and 2, Mrs. A. Tindal. 3, J. Booth. *vhc.* J. Turner. Black.—1, T. Aspden. 2, A. Darby. Cockerel.—1, E.

stiles, jun. 2, R. Walton. 3, Ridley & Dye. *vhc*, P. H. Hutchinson. *Any colour—Young Cocks—1* and Cup, Ridley & Dye. 2, J. McCulloch. 3, B. Blacklock. *vhc*, R. W. Bryce. *Blue-pied—Hens—1* and 2, R. Fulton. 3, Ridley & Dye. *vhc*, M. H. Gill. *Black-pied—Hens—1*, Cup, and 2, H. Pratt. 3, Ridley & Dye. *vhc*, M. H. Gill. *Yellow or Red-pied—Hens—1* and *vhc*, R. Fulton. 2, H. Pratt. 3, Ridley & Dye. *White—Hens—1* and Cup, Mrs. Ladd. 2, R. Fulton. 3, H. Pratt. *vhc*, R. W. Bryce. 2, J. Nicholson. *Any colour—Young Hens—1*, Cup, and 2, W. J. Nicholas. 3, R. Fulton. *vhc*, E. Beckwith. *Figmy or Austrian—Cock—1* and Cup, R. Fulton. 2, H. W. Webb. 3, C. B. Child. *vhc*, W. B. Tegetmeier. *Hen—1*, G. Holloway, jun. 2 and *vhc*, W. B. Tegetmeier. 3, C. B. Child.

**CARRIERS.—Black—Cocks—1 and Cup, H. M. Maynard. 2, R. Fulton. 3, M. Hedley. *Hens—1* and Cup, H. M. Maynard. 2, E. Beckwith. 3, H. Heritage. *Young Cocks—1*, M. Hedley. 2, Ridley & Dye. 3, R. Fulton. *Hens—1*, H. M. Maynard. 2, W. J. Nicholas. 3, M. Hedley. *Any colour—Cocks—1*, E. Jacob. 2, R. Fulton. 3, E. Beckwith. *Hens—1*, G. Bentley. 2, W. Hooker. 3, E. C. & T. H. Strath. *Black—Young Cocks—1* and Cup, T. Griffiths. 2, R. Fulton. 3, R. A. Pratt. 4, Col. Hassard. *Young Hens—1*, R. Fulton. 2, Ridley and Dye. 3, C. H. Clarke. *Dun—Young Hens—1*, R. Fulton. 2, H. Heritage. 3, H. M. Maynard. 4, Col. Hassard. *Young Cocks—1*, R. Fulton. 2, and 3, R. Fulton. *vhc*, Massey. *Blue—Young Cock—1* and Cup, B. Cant. 2, G. Kempton. 3, R. Fulton. 2, W. J. Nicholas. 3, M. Hedley. 4, G. Kempton. *Any other colour—Cock or Hen—1*, R. Cant. 2, E. Beckwith. 3, G. C. Ord. *Any other colour—1*, G. Kempton. 2, R. Fulton. 3, W. W. Pyne.**

**DRAGONS.—Blue—Cock—1, Cup, and 2, R. Woods. 2, W. B. Tegetmeier. 3, W. Smith. *Silver—Cock—1*, Cup, and 2, R. Woods. 3, W. Smith. *Yellow or Red—1*, and 2, 3, R. Woods. *Blue—Hen—1*, R. Woods. 2, W. Smith. 3, T. Frisip. *Silver Black-bar—Hen—1*, R. Woods. 2, W. Osmond. 3, J. Philpott. *Red—1*, and 2, R. Woods. 3, R. W. Bryce. 4, W. B. Tegetmeier. *Any other colour—Hen—1*, R. Woods. 2, S. C. Retty. 3, R. Fulton. *Grizzle—Cock or Hen—1* and Cup, R. Woods. 2, R. Fulton. 3, W. Smith. *White or any other colour—Cock or Hen—1*, Cup, and 3, R. Woods. 2, A. McKenzie. *Blue or Silver—Single—1*, Cup, and 2, R. Woods. 3, T. C. Burnell. 4, W. B. Tegetmeier. *Yellow or Red—Single—1*, W. Sarjeant. 2, R. Woods. 3, G. H. Thomas. *Any other colour—Single—1*, W. Smith. 2, W. Bishop. 3, R. Woods. *Any age or colour—1*, W. A. Lister. 2, R. Fulton. 3, W. W. Pyne.**

**TUMBLERS.—Almond—Cock—1, Cup, 2, and 3, T. Hallam. *vhc*, T. Hallam; H. C. Henning. N. Henderson. *Hen—1*, R. Fulton. 2 and 3, H. Yardley. *vhc*, C. Merck. *Single—1*, Cup, and 2, T. Hallam. 3, R. W. Bryce. *vhc*, W. Woodhouse; H. C. Henning. *Mottled—Cock or Hen—1*, Cup, 2, and 3, H. C. Henning. *Bald or Beards—Cock or Hen—1*, W. Woodhouse. 2, H. Yardley. 3, R. Fulton. *vhc*, D. Coombe. *Any other variety—Cock—1* and Cup, E. Beckwith. 2 and 3, T. Hallam. *Hen—1*, Cup, 2, and 3, T. Hallam. *vhc*, H. C. Henning. 3, W. Woodhouse. *Any variety—1* and 3, H. C. Henning. 2, R. Cant.**

**BABBS.—Any colour—Cock—1, M. Hedley. 2, H. M. Maynard. 3 and *vhc*, J. Firth. *Hen—1*, W. Bryce. 2, H. M. Maynard. 3, M. Hedley. *vhc*, W. J. Hyde; R. W. Bryce. *Black or Dun—Young Cock—1*, Cup, and 2, H. M. Maynard. 3, W. H. Hyde. *Young Hen—1* and 3, J. Firth. 2, W. J. Hyde. *vhc*, T. K. Cucksey. *Any other colour—Young Cock—1* and 2, M. Hedley. 3, J. Firth. *Young Hen—1*, M. Hedley. 2, R. Bryce. 3, J. Firth. *vhc*, J. Firth.**

**CHICKS.—Any colour—Cock—1, Cup, 2, and 3, H. Heritage. 3, W. Harrison. *vhc*, S. Salter; R. Fulton; A. Heath. *Hen—1*, E. E. M. Royle. 3, G. Alderton. 3, H. Heritage. *Yellow—Cock—1*, G. Hardy. 2, R. Fulton. 3, T. W. Swallow. *Hen—1* and 2, R. Fulton. 3, H. Heritage. *White—Single—1* and Cup, E. Beckwith. 2, R. Fulton. 3, J. Waters. *Any other colour—Single—1*, J. J. Frame. 2, H. Heritage. 3, J. Thompson. *Any age or colour—1*, W. Woodhouse. 2, Miss F. Seator. 3, J. Frame.**

**RUNTS.—White—Cock—1, Cup, 2, and 3, R. Sarjeantson. 2, Q. Bluhm. *Hen—E. Beckwith.* 2, J. F. Loversidge. 3, J. F. Loversidge. *Any other colour—Single—1*, H. Yardley. 2, Q. Bluhm. 3, J. E. Spence.**

**NUNS.—Any colour—Single—1, T. C. Burnell. 2, W. E. Easton. *TEGETMEIERS.—Any colour—Single—1* and Cup, C. J. Woodford. 2, P. H. Hutchinson. 3, J. Lederer. *vhc*, P. H. Hutchinson; E. Beckwith.**

**OWLS.—English—Cock—1 and Cup, G. E. Sandon. 2, A. Dathie. 3, E. Lees. *Hen—1*, W. J. Slansky. *Single—1*, J. Barnes. 2, J. Gardner. *Foreign—Single—1*, N. B. Brown. 2, R. Fulton. 3, G. Alderton.**

**TURBIS.—Blue and Silver—Single—1 and Cup, S. Salter. 2, R. Woods. 3, M. S. Temple. *Red or Yellow—Single—1* and 2, C. A. Crafer. 3, R. Fulton. *Any other colour—Single—1*, O. E. Cresswell. 2 and 3, S. Salter.**

**MAGPIES.—Single—1 and 2, Rev. F. P. Bulley. 3, E. Beckwith.**

**ARCHANGELS.—Single—1 and 3, R. Wilkinson. 2, Dr. J. Bowes.**

**RUNTS.—Cock—1 and Cup, J. T. Price. 2 and 3, T. D. Green. *Hen—1* and 2, T. D. Green.**

**TUMBLERS.—Flying, not Short-faced.—Single—1, R. Woods. 2 and 3, J. G. Frith.**

**ANTWERPS.—Short-faced.—Single—1, R. & J. Ercroft. 2, J. Gardner. 3, F. Winer. *Homing—Cock—1*, A. A. Cleaver. 2, J. W. Barker. 3, C. G. Butler. 4, G. J. Lenny. *Hen—1* and 2, G. J. Lenny. 3, T. G. Ledger.**

**ANY OTHER VARIETY—1, R. W. Bryce. 2, E. Beckwith.**

**ANY OTHER VARIETY—Single—1, R. W. Bryce. 2, E. Beckwith. 3, H. A. Roper. 4, R. Fulton. *vhc*, G. Murphy. *Pair—1*, G. Murphy. 2, G. H. Gregory. 3, J. D. Firth. 4, B. W. Browne.**

**COLLECTION OF FOUR PAIRS OF PIGEONS (Exclusive of Carriers, Pouters, and Tumblers)—Not less than two varieties.—1, Cup, and 2, R. Fulton. 3, A. Hives.**

**COLLECTION OF CARRIERS, POUTERS, BARBS, or TUMBLERS.—Four birds of any or any varieties to be shown in a pen.—Young—1, H. M. Maynard. 2, T. Hallam. 3, J. Firth.**

**COLLECTION OF ANY OTHER VARIETY.—Four birds of one or any varieties to be shown in a pen.—Young—1 and Cup, F. P. Bulley. *Equal 2*, Ward and Rhodes, J. Schwitzer. *Equal 3*, T. Patman, J. Schwitzer. *vhc*, J. T. Price, J. Philpott.**

**HOMING ANTWERPS.—Special Flying Class—Cock—1, W. S. Marsh. 2, J. Edmonds. 3, Coppard & Son. 4, Col. Hassard. 5, G. C. Carvill. *Hen—1* and Cup, G. Cotton. 2, J. J. Sparrow. 3, W. B. Tegetmeier. 4, T. G. Ledger. 5, Roff & May.**

THE DINNER.

This meeting of fanciers took place on Tuesday evening in the Marble Hall. Mr. Sawyer performed a capital repast. The chair was taken by J. K. Fowler, Esq., one of our oldest and most honoured fanciers, and we are sure that all there present must have felt much indebted to him for the very able and courteous way in which he presided. He was supported on his right by Mr. Howard, and on the left by Mr. Smith. Among the company we noticed Lord St. Leonards, the Hon. and Rev. F. Dutton, Messrs. Hewitt, Crook, Prior, Teebay, Nicholls, Dixon, Tegetmeier, P. H. Jones, Esquilant, Darby, W. A. Burnell, Cresswell, Wright, Salter, Hibbert, R. R. Fowler, Mathews, Fitz-Herbert, Davis, E. Jones, Boissier, Adkins, J. Walker, Sainsbury, Gedney, Cameron, &c.

After dinner the usual loyal toasts were proposed and warmly received; and then followed the healths of the Judges, to which Mr. Hewitt responded, and we were delighted to find he has no partiality for the "untrimmed classes" which we wrote against a week or two back. The healths of the Committee, Secretary,

splendid feather, second to a very White-crested Black Poland in equally good feather, and third to a very neat Silky. In the class for hens a splendid White-crested Black Poland, with an immense globular crest, was first; a very square White Dorking second; and a good Silver Poland third. It was a pity the Committee had not given this latter breed a class. In the *Bantams* the Game were but indifferent, while in the Variety classes most of the prizes went to Laced birds. Of them the first Silver cockerel and first Gold pullet were very perfect. The *Waterfowl* made excellent classes. The cup *Aylesburys* had fine beaks, and were massive in frame. The *Rouens* were capital; while in the next class a very good pen of Black East Indians were first, the Duck being especially free from brown on the wings. The pen of this breed shown by Mr. Sainsbury were very good, and closely pressed on the first in our opinion. The third Calls were pretty, and we were glad to see the breed in the list. The Sale classes were large, good White Cochins winning both first prizes.

The *Pigeons* were an attractive little lot. The first Jacobins were good Reds. A moderate pair of White Fans were first in their class. The cup went most deservedly to Mr. Yardley's Black Carrier cock. The Tumblers were good; first and second going to Almonds, and third to Kites. The Dragons mustered well; Blues of good colour and sound in wing-bars won first and second. We noticed but moderate birds in the Sale class. We furnish full awards below, and wish the Society, which has made such a capital start with amateur judging, very much success. The room was well lined with visitors, so we hope the receipts at the gates were good.

**POULTRY.—BANTAMS.**—Light.—Cock.—1, R. P. Percival. 2, T. A. Dean. 3, Mrs. W. C. Drummond. Hen.—Cup, S. Sambrooke. 2, R. P. Percival. 3, T. A. Dean. *Chc.*, J. Bloodworth. *Dark*.—Cock.—1, J. S. Maggs. 2, R. P. Percival. 3, G. Carson. 4, R. P. Percival. 5, Morris & Cameron. *Cochins*.—*Cinnamon* and *Buff*.—Cock.—1, R. E. Fowler. 2, R. P. Percival. 3, S. R. Harris. Hen.—1, J. E. Swindle. 2, J. Bloodworth. 3, A. Darby. *Any other variety*.—Cock.—1, R. A. Boissier. 2, R. P. Percival. 3, Rev. H. J. Borrow. *Chc.*, A. Darby, Rev. R. S. Woodgate. *Hens*.—1, Rev. H. J. Borrow. 2, C. Bloodworth. 3, Rev. R. S. Woodgate. *Chc.*, Mrs. J. T. Holmes. **GAME.**—*Black-breasted*.—Cock.—Cup, G. Newdigate. 2, T. P. Lyon. 3, P. A. Beck. 4, J. S. Maggs. 5, T. P. Lyon. 6, W. H. Stagg. *Extra*.—Cup, G. Newdigate. *Chc.*, J. P. James. *Brown*.—Cock.—1, T. Mason. 2, H. E. Martin. 3, G. F. Ward. *Any other variety*.—Cock.—1, T. Mason. 2, H. E. Martin. 3, G. F. Ward. *Any other variety*.—Cock.—1, W. H. Stagg. 2, W. C. Phillips. 3, H. E. Martin. *Hen*.—1, W. C. Phillips. 2, D. W. J. Thomas. 3, C. Gibbs. **HAMBURGERS.**—*Gold and Silver-spangled*.—Cock.—1 and 2, H. Feast. 3, H. Pickles. *Hen*.—1, H. Feast. 2, H. Feast. 3, T. Blakeman. *Gold and Silver-pencilled*.—1, H. Feast. 2, J. Long. 3, W. K. Ticker. *Hen*.—1, H. Feast. 2, W. K. Ticker. 3, H. H. Thompson. *Black*.—Cock.—1, E. L. Garnett. 2, H. Pickles. 3, H. Feast. *Hen*.—1, H. Feast. 2, R. L. Garnett. 3, H. Pickles. **FRENCH.**—Cock.—1, H. Feast. 2, S. A. Vickary. 3, J. H. Brooks. *Hen*.—1, R. E. Fowler. 2, S. W. Thomas. 3, E. Burrell. *Chc.*, H. Feast. **LEGHORN.**—*Brown*.—1, F. L. Green. 2, A. Kitchen. 3, S. L. Bradbury. *White*.—1 and 3, R. R. Fowler. 2, E. C. Seaman. **BANTAMS.**—*Game*.—*Black Red*.—Cock.—1, W. Adams. 2, G. Prentice. 3, W. Hicks. *Hen*.—1, W. Adams. 2, J. Smith. 3, E. C. Phillips. *Game*.—*Any other variety*.—Cock.—1, W. C. Phillips. 2, G. H. Fitz-Herbert. 3, E. S. Hockaday. *Hen*.—1, F. Maitland. 2, W. M. Rumbelow. 3, T. S. Hockaday. *Any other variety*.—Cock.—1, T. P. Carver. 2, W. H. Robinson. 3, G. Holloway. *Hen*.—1 and 3, J. W. Lloyd. 2, G. Holloway. **ANY OTHER DISTINCT VARIETY.**—Cock.—1, C. Bloodworth. 2, A. Darby. 3, Rev. R. S. Woodgate. *Chc.*, H. J. Lonnnon. *Hen*.—1, T. Norwood. 2, A. Darby. 3, C. Bloodworth. *Any other variety*.—Cock.—1, T. Fereman. **SELLING CLASSES.**—Cock.—1, R. A. Boissier. 2, C. Sidgwick. 3, W. Jones. 4, C. Bloodworth. *Hen*.—1, C. Bloodworth. 2, J. Bloodworth. 3, H. Haddrell. 4, E. Fritchard. **WATERFOWL.**—*Pair*.—1, G. Hanks. 2, W. H. Coppelstone. 3, J. S. Maggs. 4, H. Feast. **DUCK.**—*Brown*.—1, H. J. Bailey. 2, J. S. Maggs. 3, E. Snell. *Aylesbury*.—1, R. E. Fowler. 2, H. J. Bailey. 3, E. Snell. *Any other variety*.—1, S. Burn. 2, W. R. Rootes. 3, H. J. Bailey. **GESE.**—1, R. E. Fowler. 2, E. Snell. 3, H. J. Bailey. **DOONS.**—*CARRIERS.*—Cock or Hen.—Cup, H. Yardley. 2, J. James. 3, W. G. Flanagan. *DRAGON.*—Cock or Hen.—1, C. W. Calcutt. 2, J. James. 3, G. S. Prentice. *Chc.*, W. G. Flanagan. *Any other colour.*—Cock or Hen.—1, W. G. Flanagan. 2, A. McKenzie. 3, G. S. Prentice. **TUMBLERS.**—*Short-faced*.—Cock or Hen.—1, W. R. Pratt. 2, H. Yardley. 3, G. Packham. *Any other variety.*—Cock or Hen.—1 and 3, J. Aston. 2, Master E. P. Harmer. **ANTWERPS.**—*Short-faced*.—Cock or Hen.—1 and 2, H. Yardley. 3, C. F. Copeman. **FANTAILS.**—Cock or Hen.—1, J. Walker. 2 and 3, J. F. Loveridge. **JACOBINS.**—Cock or Hen.—1, P. H. Jones. 2 and 3, G. S. Prentice. **OWLS.**—Cock or Hen.—1, A. J. Barnes. 2 and 3, P. H. Jones. **RENTS.**—Cock or Hen.—1, T. D. Green. 2 and 3, H. Yardley. **ANY OTHER DISTINCT VARIETY.**—Cock or Hen.—1, H. Yardley. 2 and *Chc.*, P. H. Jones. 3, Mrs. J. T. Holmes. **SELLING CLASS.**—1, G. Packham. 2, A. Shadling. 3, A. P. Byford.

## PRESERVING EGGS.

In the year 1871-2 I preserved eggs so perfectly that after a lapse of six months they were mistaken when brought to table for fresh-laid eggs, and I believe they would have kept equally good for twelve months.

My mode of preservation was to varnish the eggs as soon after they were laid as possible with a thin copal varnish, taking care that the whole of the shell was covered with the varnish. I subsequently found that by painting the eggs with fresh albumen beaten up with a little salt they were preserved equally well, and for as long a period. After varnishing or painting with albumen I lay the eggs upon rough blotting paper, as I found that when allowed to rest till dry upon a plate or on the table the albumen stuck so fast to the table or plate as to take away a chip out of the shell. This is entirely obviated by the use of the blotting paper. I pack the eggs in boxes of dry bran.—DEE SIDE.—(*World of Science*.)

THE BIRMINGHAM AGRICULTURAL EXHIBITION SOCIETY.—The Poultry Show is open for the first time to non-subscribers, the

fee for a single pen being 8s. and for Pigeons 5s. This concession should increase the number of exhibitors considerably. Should this be the case there will be very little room remaining for the exhibitors of implements and miscellaneous articles, the entries for which are already closed, although the allotment of space cannot take place until the stock and poultry certificates are enumerated.

CANTERBURY POULTRY, PIGEON, AND CANARY SHOW.—The entries close on the 20th. Since the publication of the schedule two extra prizes are given, one (£4) for pair of Light Brahma pullets, and one (£5 5s.) for best cockerel and pullet Silver-Grey Dorkings, making fourteen prizes besides the money prizes.

## EXCHANGE OF QUEENS.

THIS autumn I substituted in September two imported Italian queens in place of two common English queens, both of which having escaped from their careless owners (unknown to me) took up their quarters in my garden, one this and one last year. Both hives took to their stranger queens with the greatest complaisance within six or seven hours of the removal of their own mother queens, and without the slightest symptom of disaffection. I gave these queens to the several hives in my own old fashion—that is, by isolating the queen from her Italian guards under a broken wineglass, and putting her over a central hole at the top of each hive, with the intervention of a bit of perforated zinc. I had intended to try queen cages, two of which I bought for the purpose; but my friends here wishing to see the process of union and how the bees would take to the new queen, I resorted to the plan which I have always hitherto adopted as described above. My plan is to let the queen get thoroughly scented with the warm odours of the hive below and to make acquaintance with the excited bees beneath her, many of which, having discovered their own loss, are only too glad to scent and touch the solitary queen, which they do by thrusting their probosces through the holes of the zinc. When the queen, who places herself invariably just over the hole, has been thus well scented and the mutual acquaintance has been made, I gently withdraw the zinc so as to admit one bee at a time into the glass. If all goes well I let up another and another, and so on till I am satisfied by the joyful humming of the bees above and below that all danger of an attack upon the queen is over. They are then left to their own devices, and sooner or later the whole party descend and are seen no more.

In the one case thus treated early in September no result appeared, though I was satisfied all was well, till towards the end of October, when I had the pleasure of seeing several well-marked Italians in the hive, which will no doubt so increase during the winter and spring that by May the whole hive will be italianised.

The other hive received the queen most cordially, and in this case I had the pleasure of seeing her descend from the wineglass into the hive below, welcomed and accompanied by a handsome body guard of admirers and happy bees within twelve hours from the time I had deprived them of their old queen. But there arose a subsequent question in my mind as to whether after all some fatal accident had not befallen her, for the bees resumed (perhaps continued) their restlessness the next day, appearing to have lost their queen, or not to have recognised the Italian. I also feared that she was still a virgin queen because her own guards did not seem to take much notice of her before I took her from them, and I distinctly heard her pipe while still in the box she travelled in. Therefore I thought it prudent to restore to them their old queen (saved against accidents) towards the evening of the second day. She, too, though absent some thirty hours from the hive, was received back again and escorted into the hive much as the Italian had been the day before. Of course I thought the Italian queen had been sacrificed, perhaps by queen-encasement, as is frequently the case. However, since then a great number of well-marked yellow-jackets have appeared in the hive.

I can only suppose the explanation of this curious circumstance to be this, that the stranger queen was recognised and received by a portion of the bees only, among which she took up her position quietly in some corner of the hive, and that the mass of the bees not having come across her were still in agitation when I gave them their old queen. Afterwards, I presume, the two queens must have met, and the Italian proved herself the stronger. Of course it is possible the two queens may be alive, and have amicably divided the kingdom between them. Such a possibility is vouched for by undoubted instances, however rare and exceptional, having been recorded in the pages of this Journal of two queens being found together in the same hive, although it does not follow that they were both mother queens.—B. & W.

SILVER-GRAY DORKING CUP AND ARCHANGEL PRIZES AT THE CRYSTAL PALACE.—Through your columns I acknowledge with thanks the subscriptions which I have received for the above-

mentioned prizes. *Silver-Grey Dorking Cup*: T. C. Burnell, Esq., 10s. 6d.; Hon. Mrs. Colville, 10s. 6d.; Countess of Dartmouth, £1 1s.; W. H. Denison, Esq., 10s. 6d.; Miss Pasley, 10s.; Rev. H. A. Peel, 10s. 6d.; Major Plummer, 5s.; W. Roe, Esq., jun., 5s.; James Walker, Esq., 10s. 6d. = £1 13s. 6d. *Archangel Prizes*: R. Barclay, Esq., 5s.; J. N. Bowes, Esq., 5s.; T. C. Burnell, Esq., 5s.; W. H. Denison, Esq., 5s.; R. Wilkinson, Esq., 5s. = £1 5s. The rest of the sums required I gladly make up.—O. E. CRESSWELL.

### LARGE APIARY.

Mr. J. S. HARBISON of San Diego county, Cal., arrived in this city yesterday with ten carloads of honey, each carload containing 20,000 lbs. This vast aggregation of bee labour was taken from Mr. Harbison's six apiaries on the sides of the coast range of mountains as near to the Mexican line as they well can be, and yet claim the protection of the Stars and Stripes. Twenty-five years ago Mr. Harbison made a stir in the world by selling at one time 2000 lbs. of honey, the product of his apiary near New Castle, Pa. So much honey had never before been raised by a single producer, and the sale led hundreds of staid farmers to embark in what looked like a most profitable field of industry. The result was not flattering. Short seasons and limited bee pasture forbade profitable bee-culture. Old-fashioned hives were then the only kind known. The modern means of robbing bees without killing them had not been thought of.

Having invented a hive that enabled the culturist to obtain successive crops of honey from the same colony of bees, Mr. Harbison began to look for a region that would supply food for the bees. He searched for this in the equable climate of the Pacific coast, and found it in a strip of country in the extreme south-western corner of the United States, now known as the bee belt of California. Sheep-raising was the only industry of the natives found by Mr. Harbison when he first visited the country. The country inland was thought good enough for sheep-pasturing, but no one dreamed that the soil could be made to produce grain in paying quantities. Timber was confined to the bottoms of running streams and to the canons, the valleys and hillsides being covered with a growth of stunted brushwood, from which sprang a luxuriant growth of white sage, sumach, and other flowering shrubs, which bloom there nine months of the year.

Mr. Harbison's first apiary was started on a mountain side twenty miles east of San Diego. He embarked for the west with seventy hives of bees, but they were reduced to sixty-two by casualties. From them he now has six apiaries and a total of three thousand hives. He employs fifteen men constantly, and is reaping rich profits from many thousands of acres that must otherwise have been a barren waste. He soon had many imitators, and now not less than three hundred persons are taking honey along the "Bee Belt."

The California bee season, Mr. Harbison says, begins by February 1st. In March or April the bees swarm, and the bee-culturist has lively times in saving the swarms. The science has become so systematised now that the apiculturist knows within a day or two when a given hive may be expected to swarm, and as the young bees always settle somewhere near the parent hive at least once before selecting their new quarters, a swarm is seldom lost. The flowers are at the height of their luxuriance in May and June, and the taking of honey is begun usually about May 20th, and the bees are kept at work as long as the flowers last. They cease to bloom in sufficient quantity to more than subsist the bees in the early part of August; but the little workers are able to find enough to live on without consuming their stores as late as October. It will thus be seen that the harvest time is never longer than three months, and is often much less. After October begins, although the air is still mild and spring-like, the bees cease to work, and retire into a semi-dormant condition. Once every eight or ten days a colony will turn out at mid-day and fly around an hour or two in the sunshine, but they never fly far from the hive, and are never seen at work.

The food of the bees in the bee belt is generally the flower of the white sage, a plant that closely resembles the garden sage. This is not to be confounded with the sage bush of Nevada and Utah, which is of the wormwood species, and has the family bitterness. Next to the sage in importance as bee food is the sumach, a shrub that grows in California without poisonous quality. In fact, there is no poisonous flowering plant in the bee range, and the honey has none of the colicky qualities that make eastern-grown honey objectionable. The honey is graded by the culturist according to the plant from which it is derived. That from sage flowers, being clearest and most aromatic, is most valuable.

Mr. Harbison says that notwithstanding the great crop that he has brought into this market, he will probably not realise more than \$1000 after deducting expenses and interest on capital. He had to dig his bee ranch out of the wilderness. The roads thereto over rocky mountain sides and deep canons, were built

at heavy cost. The continuous labour of fifteen men is needed in the care of propagation and harvesting. The hives, boxes for shipment, and household supplies have all to be transported from San Diego, forty miles from his most remote apiary. It costs about four cents, gold, to freight a pound of honey by water to San Francisco and by rail to New York. Taking into consideration the commissions and currency values realised here, there is no great margin left for profit.—(New York Sun.)

### OUR LETTER BOX.

**FATTENING TURKEYS (Anxious).**—If you mean to have fat and weight at Christmas you must begin to think about your Turkeys. If you mean them to be very fat they should be up at least a month, and now they should be very well fed, although not shut up. You must choose a house in which they can roost. They do not care so much about being very high, but they must roost somewhere. The empty bay of a barn will make a place if no other is available; perches are easily improvised. The birds should feed from a trough, and, unlike other poultry when fattening, they may always have food by them, but that must not be abused. They must be fed frequently, but with fresh food. The trough is not to be filled in the morning for the day. The meaning of always having food by them is that whenever the trough is empty a little food should be put in. No poultry will fatten on sour or stale food. The food should be barley meal or ground oats flaked with milk, with onion tops chopped fine and mixed with it. Many successful feeders add a little bean or pea-meal with the food. They should not have too much room. They should be supplied with gravel and fresh-cut sods of grass. Their food should be made into a thick liquid, not a stiff paste.

### REMARKS.

- 8th.—White frost in morning; fine day; two very slight showers, and a low temperature.  
9th.—Rather dull morning; a fine day, but colder than the one preceding.  
10th.—Fine all day, but still getting colder.  
11th.—Fine day, but very cold; solar halo at 3 P.M.; wind high at 8 P.M.  
12th.—Rain from soon after midnight on 11th to 9 A.M. on 12th, then fine for a short time, then frequent (and at times heavy) showers.  
13th.—Very damp, dark, and thick in the morning; dull and showery all day, and warmer.  
14th.—Foggy morning, but clearing off soon after 9 A.M.: the remainder of the day fine; very warm at night, 9 P.M. temperature 58°.  
The average temperature of the week about 5° below that of the previous one, the first five days having been cold and frosty.—G. J. SYMONS.

### COVENT GARDEN MARKET.—NOVEMBER 15.

LARGE quantities of American Apples are still arriving. Pears continue to reach us from Jersey in sufficient quantities to meet the demand.

From observations taken near London during forty-three years, the average day temperature of the week is 48.0°; and its night temperature 33.4°.

## FOLIAGE IN RELATION TO COLOURING AND FLAVOURING FRUITS.

OR an unscientific gardener to attempt to write on a scientific subject may savour of presumptuousness, but my excuse is that learners in the practical part of our profession are helped more by their fellow learners than they are by articles elaborately written by the most talented men of science. We can grope our way together, as it were, feeling and sympathising with each other. Occasionally one is able to give the others a

pull, and if it is not in the right direction there are plenty to apply the drag. We are, I own, sadly behind in theoretic knowledge, but I think I have read somewhere that "the greatest of men have very small swallows," and of course the little men cannot be expected to take in a whole cyclopædia at once. Professors of science are generally highly educated men whose language is of necessity beyond the comprehension of ordinary gardeners; and although they are generally right in their conclusions, yet, owing to their want of practical knowledge, they are, of course, sometimes wrong. I hope it is not a general failing of gardeners, but I must own to the possession of it myself, that I would rather listen to the rough original reasonings of one of Nature's children unadorned with scientific education, but with a taste for observing every-day things, than I would read the reports in the *Times* of great scientific meetings. Perhaps the reason is that the observant gardener has so much delightful food for his mind that it makes him dainty, or in my case it may be mere laziness, reaching no further than the spot on which I stand. Let us hope so. I know I ought to have read myself up on the subject of this article, but then there would have been a disadvantage, for if I read I might be tempted to copy. Now, if not strictly correct I am at least original, and may tempt some of my fellow-workers to think for themselves.

A great many complaints have appeared in the gardening papers this season about Melons without flavour and Grapes without colour, and as no satisfactory explanation, as far as I have seen, has been given, I will attempt to give my own ideas of the matter.

A certain proportion of healthy foliage is absolutely necessary to elaborate the juices for growing, colouring, and flavouring fruits. If the foliage is injured by scorching, by insects, or any other means, the fruit must suffer. The past summer has been an exceptional one, and plants required exceptional treatment. Three times the usual quantity of water was necessary, and where it was not applied, in addition to the plants being starved, red spider and other insects would so mutilate the leaves that they could not properly perform their functions. I have often said that Vines, as a rule, do not have sufficient water, and the same applies to Melons. It is one of the greatest mistakes in fruit-culture to keep Melons dry when they are approaching maturity. I suppose the variety I cultivate exclusively (Meredith's Cashmere) is one of the

most difficult to keep from cracking, yet I would on no account keep it dry as a preventive of its only fault, for by so doing the flavour becomes very poor indeed. I prefer crippling the stalk of the fruit, so as to limit its supply of sap without checking the supply to the foliage. The stalk is squeezed between the finger and thumb, and it often requires doing daily, as the wounds soon heal. One, if not the principal, cause of the cracking of Melons is from a too limited supply of water. When the plants and fruits are young and require to grow vigorously they get into a partially hidebound state, and afterwards when the fruit expands to its natural size the skin has lost its elasticity and is forced open.

A heavy soil approaching to clay, and sufficiently rich to require nothing mixed with it, grows the best Melons. Manure makes them coarse in texture and deficient in flavour; so that when soil can be procured rich enough of itself it is better if the roots do not come in contact with manure at all.

I have said that foliage is required in proportion to the fruit. In addition to this I believe that in a hot season with a dry atmosphere, owing to greater evaporation going on, greater appropriation, too, of the juices by the fruit, and probably a greater waste also, that more foliage in proportion to the quantity of fruit is required than in a season with a humid atmosphere; but in practice the reverse of this happens. The foliage is left in the usual proportion, but the hotter and drier the weather the more it is injured by insects and scorching, and too often nothing is done to alleviate the mischief either by allowing the shoots to ramble a little, reducing the quantity of fruit, or supplying more water than in an ordinary, or even an exceptionally, wet season.

To second these remarks I may say—firstly, that my fruit on the whole has not been below the average in quality this season; secondly, that I never knew of an instance of good-flavoured fruit of any kind where the plants were badly infested with red spider, or the foliage much injured by scorching or otherwise; thirdly, that as I, in common with many others, made the mistake of planting Madresfield Court Grape in a late vinery, and am obliged to give it exceptional treatment to prevent it cracking either by withholding water or reducing its foliage (the latter method I prefer, as its roots are in company with others requiring water), I shortened it back last season to two or three leaves beyond the fruit when it was about three parts coloured, and it finished off very well without cracking. This season, a much drier one, the same treatment not only prevented cracking, but the Grapes never finished colouring, while other kinds in the same house are perfect. I have no hesitation in saying that had I left a few more leaves the Madresfield Court Grape would have finished thoroughly; but it is a difficult matter to know how to act to a nicety, and to be certain of growing this noble Grape to perfection it should be grown with the Black Hamburg or other early Grapes.

With regard to Grapes losing colour after they have once been black, I think it is in cases of insufficient

ripening (that this occurs; for remember, well-grown Grapes, even of the Hamburg class, are coloured long before they are thoroughly ripe, and often swell considerably after they are coloured. I think, then, that even in the case of Hamburgs, if they are intended to be kept for any considerable time, the temperature should not be much reduced till they have been coloured a fortnight or three weeks, say nine or ten weeks after they commence colouring. When the fruit is intended for immediate use this is not of so much importance.

I find I have nearly filled my paper with preface, and I hope to go on with the subject at a future time.—WM. TAYLOR.

## A GARDEN OF HARDY FLOWERS.—No. 2.

### THE PERENNIAL BORDER.

WHAT is a perennial border? According to ordinary examples it is a confused intermixture of hardy flowers thrown together without order, and with a predominant air of untidiness that robs it of any approach to that which is graceful, beautiful, or ornamental. This is a matter for regret, because such borders afford peculiar facilities for the enjoyment of something that is bright and lovely at all seasons of the year, and by the exercise of a little care in arranging the plants the repellent ugliness, which is the but-too-common characteristic of so many of the borders, might easily be avoided, and a scene of quiet beauty—a collection of treasures rich and rare—be offered so effectively as to render it by no means a place to avoid or a sight to disgust, as I have heard said of some of the borders to which I allude.

I happen just now to be making a perennial border, and in thinking over the matter it appears to me that there are two ways of treating this part of a garden. Narrow strips of some 5 or 6 feet wide should have the plants arranged singly, treating even those possessing the minute growth of an Alpine as specimen plants or tufts. This individuality should be strictly maintained in the body of the border, keeping all the plants far enough apart to afford "ample space and verge enough," not only for the full development of each one, but to afford an unobstructed view of it. An edging of one kind of dwarf compact growth along the front margin is as admissible as it is desirable, imparting as it does an air of neatness and finish to the whole. While graduating the plants according to height, from the dwarf edging in front up to the tallest plants behind, I would by no means confine all the tall plants to the back, but would select a few of the most striking for prominent positions along the centre to impart variety and afford relief.

In very wide borders, of say 20 feet or upwards, a bolder style of arrangement should be adopted. Groups of a dozen or more plants of the same kind, a row or two of Hollyhocks at the back, edgings and margins *ad libitum* in front, groups or colonies of many varieties of one species, or even comprising many species of one genus, the intersecting spaces being filled with mixed specimens, treated in the same way as in our narrow border. Such an arrangement would always be as interesting as it would be ornamental. The groups would form a most important feature, enabling one while enjoying the beauty of the whole to contrast form with form, to obtain a clear idea of the relative value of the different varieties, to subject new introductions to the crucial test of comparison with all the best kinds of established merit, and thus become a constant source of attraction and afford valuable instruction. If a still more striking effect is wished for, nothing is easier than to substitute bands and lines of massed colours for the mixed plants which enclose the groups, or the groups themselves might consist of one colour only; but this plan would undoubtedly rob the border of much of its merit, and I do not recommend its general application.

In proceeding to the selection of a few good kinds for beginners to start with I would ask them not to regard any of the lists as by any means exhaustive, but rather as embracing a few choice kinds to form the nucleus of future collections, which experience will enable them to add to from time to time. The plants for groups should consist of species having many varieties. Of these the Phloxes form a most important family, growing quickly into large clumps of 2 to 3 feet high, with colours ranging from pure white to deep purple. There are two species which are especially worthy of general cultivation, *P. suffruticosa* and *P. decussata*, both having numerous varieties; and as the first is early and the last late-flowering, a mixture of both is certainly desirable. Of the *suffruticosa* section we may take Pearl, William Paul, Purple Emperor, Mauve Queen, Lady Abercromby, Lewis Kidd, William Young,

Stella, Princess of Wales, John Baillie, Marquise, and Her Majesty; and of *decussata*, where we find more varied colours, we will choose Lothair, Deliverance, Amabilis, Ruby Queen, Purple Prince, Coquette de Parc de Neuilly, Madame Moisset, Monsieur Conrad, Mrs. Laing, Mrs. Dombrain, Venus, and Queen of Whites. Of Pentstemons a list has already been given. Of the *Dianthus* family, *barbatus*, better known by its familiar appellation of Sweet William, forms most brilliant groups. *Antirrhinums*, *Pyrethrums*, *Columbines*, *Carnations*, and herbaceous *Pæonies* are all valuable subjects for this purpose. Mr. Abbey has lately given a good selection of these *Pæonies*, and for a choice dozen of *Pyrethrums* take Progress, Virginal, Boule de Neige, Nemesis, Delicata, H. Schmidt, Sol-faterre, Princess Charlotte, Chamois, Peau Rouge, Duchesse de Brabant, and *Imbricatum plenum*.

For other prominent positions I would include many old favourites, such as Lavender, Rosemary, the old monthly China Rose, bright with gay flowers even at this late period of the year; the fine yellow Evening Primrose (*Oenothera gigantea*), Moss Roses, with some of the Delphiniums, such as *elatum* and *formosum*, with the tall-growing *Campanulas*, the *Tritomas*, and *Fuchsia Riccartoni*.

For an edging nothing can be better than a broad line of the old white Pink. The deep lavender-flowered *Nepeta tenacifolia* also forms a capital margin, while for variety we have all the *Viola* tribe; or for greater neatness and precision we may turn to such hardy succulents as *Sempervivum californicum*, *S. montanum*, and the pretty little pearly *Sedum glaucum*.

At this season of the year *Chrysanthemums* become most important in our borders. Like most popular flowers the varieties abound, being numbered by hundreds; all are ornamental, but I will select for the border—of Japanese sorts—Fair Maid of Guernsey, Elaine, James Salter, Dr. Masters, and Prince Satsuma. Of the old large-flowered section—*Jardin des Plantes*, Queen of England, Lord Derby, George Peabody, Hetty Barker, Prince Albert, Julie Lagravère, Isabella Bott, Guernsey Nugget, and Princess Beatrice. Of the Pompons, one of the most valuable is Bob, an excellent old crimson sort, with Madame Marthas, Lizzie Holmes, White Trevenna, Brilliant, Firefly, Sidonia, and Atala.

For specimens and clumps of other flowers I may take *Iris germanica*, *I. amena*, *I. subbiflora*, *I. flavescens*; the *Geums*, *Narcissi*, *Liliums*, *Gentians*, *Dodecatheons*, *Lupines*, *Campanulas*, *Anemones*, *Arabis*, *Veronicas*, *Spiræas*, with Wallflowers, Poppies, Pinks, Picotees, Potentillas, Scabious, Foxgloves, *Rudbeckia hirta*, *Helleborus niger*, *Arabis verna*, and all the Rock Roses.—EDWARD LUCKHURST.

## WINTERING LETTUCES.

MANY are the gardeners who have little or no glass accommodation, yet who are expected to have Lettuces, if not all the year round, at any rate as early in the summer as possible. Many amateurs also are there who particularly desire a supply of salads during the first warm days of summer, yet both of these—amateurs and gardeners—frequently fail in preserving their Lettuce plants through the winter. When this is the case disappointment is sure to follow, for from spring-sown seed Lettuces cannot be produced until half the summer is over, and therefore every effort must be made to preserve their September-sown plants. But it has not unfrequently happened that their plants have been killed, not by the want of endeavours to protect them, but because of the care that has been taken in sheltering the plants.

For some years I have had to grow Lettuces without the aid of either frames or hand-lights, and only once have I failed to preserve my autumn-sown plants. I shall not soon forget that failure, for throughout the months of April, May, and June the cry for Lettuces was continual, and I had none wherewith to answer it. I lost my Lettuces by what may be described as "placing all my eggs in one basket." True, it was considered as being the best basket, but that did not diminish the inconvenience of the failure. I planted all my Lettuces at the base of a south wall. What place than that could be regarded as more sheltered? None in my case, yet it failed to preserve the plants, as it has now and then failed since; but then I have had plants in other places which, though at first sight might be considered as unsuitable places, have in the end proved their worth.

The great protector of Lettuce plants during the winter is snow, and the foot of a south wall is the first place in the garden from which the snow melts. If after that a long term

of severe frost follows, the Lettuces are killed. I still plant Lettuces at the front of the south wall, and if they survive they there come into use early; but I also plant others in a very exposed place in the garden, not in rich but in porous soil, for if the water cannot pass from the surface freely the Lettuces will decay. The snow has almost invariably preserved these Lettuces from the killing effects of frost, but I generally lost many from the effects of excessive wet. To obviate this I made rather deep drills, filling these with ashes, and in these planting the Lettuces. Since adopting that practice I have seldom lost any plants. If the plants on the south border succeed, these in the open give a good succession to them; but if the sheltered plants fail by the early melting of the snow a portion of the plants are removed from the ashes on the first signs of spring and are planted in their place. Thus I manage to have a full supply of plants, and have them ready for cutting as soon as it is possible to do so with the conveniences at my disposal. To risk all my plants near the south wall is to risk failure, and to plant entirely in the open and leave them there to heart is to be unpleasantly late with summer salad; but by availing myself of the advantages of both sites I have not failed to preserve the plants and have a full supply of Lettuces in late spring and early summer—the very time when they have been most appreciated. For fifteen years consecutively that plan has been successful, and my neighbour, the gardener at the Hall, says that it is worthy of mention.

It is surprising how well the Lettuces root in pure ashes—much better than in the ordinary garden soil, and plants in the ashes are rarely injured by slugs. I suspect that the soil is too wet for the roots to work freely in the winter, but superfluous water passing quickly through the ashes and admitting the air, enables roots to form and which do not perish.

I have derived many useful hints from the *Journal* and venture to give this in return, which may possibly be useful to some other—GROOM AND GARDENER.

### THE ROSE ELECTION—STRAWBERRIES.

I NEVER before knew who raised *Souvenir de la Malmaison*. All, except Général Jacqueminot, are rightly named and accredited. The Général was raised by Rousselet, not by Rouplet. It is evidently an error; the long *s* being confounded with a *p*. I received a most kind letter from a valued friend and correspondent, Mr. Ferdinand Gloede, some time back from his place in Germany, saying that *Perle de Lyon* was better than *Maréchal Niel*. What say the rosarians of England? Mr. Gloede lives at Oppendorf or Eppendorf in Germany.

If the readers of the *Journal of Horticulture* want an opinion on Strawberries they may depend on Mr. Gloede. He is, moreover, a most excellent packer of Strawberry plants. I have received in times past Strawberry plants from Les Sablons, France, far fresher than plants packed a few miles off. You are sure of the sort applied for being sent true. I owe him a deep debt of gratitude for supplying me with Rivers's *Eliza*. It is one of the best Strawberries known. It is a tufted plant, perfect in shape, and a sure and abundant cropper at all times, and especially in critical seasons.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

### DECIDUOUS TREES AND SHRUBS.—No. 3.

It is not unusual to seek to disguise the boundary of a park by a belt of trees. This is also one of the most common methods of marking the boundary of estates; but we must not lose sight of the fact that in all pleasing landscapes there is a total absence of formality, and that the aim of the planter should be to produce Nature in her best guise, not imitating her rugged, cold, and cheerless aspects. It is a mistake to limit the prospect of an estate by belts of trees or close narrow plantations, which are often obstructive of the best views of natural scenery. In treating of rural scenery, however, we often have the straight lines of hedges and roads to disguise. Surely this can be effected without employing an unvaried belt of trees. The road being straight, there is no reason for making the outline of the trees straight and having them of unvaried height and breadth. Shrub-like trees, as Holly or Thorns, will serve for disguising a road quite as effectively as taller trees. Sharp turns may be converted into graceful sweeps, or made to appear so by judicious planting—a straight margin being an eyesore. Rows of trees may often by judicious thinning be made contributory to the landscape. By

leaving all the best trees the appearance of age is imparted. It will usually be found that in a well-timbered country we have little to do but clear, adding such trees as will impart variety, though of an allied character to the trees existing. The complete removal of lines of trees from hedges would result in barrenness, and render more apparent the outlines of the roads and fences. It is the common subjects that give rural scenery its character. An artificial scene is never equal to the natural, or that in which least art and most nature is apparent. However pleasing it may be to the imagination, it is practically a mistake to imitate nature, or seek to produce nature itself in rural scenery. To do that it would be necessary to efface culture, and if by so doing no better reward attend our efforts than is exhibited by a majority of parks, the less said of such imitations the better. Provided the fences are low and well kept, they do not materially prejudice the view. What we wish to impart to highly cultivated ground is as much natural beauty as circumstances admit, having in view utility.

I will now briefly refer to avenues. These are often admired, but upon what principle they were conceived it is difficult to imagine, for we not unfrequently see them stretching across picturesque ground, cutting it in twain and marring its beauty. They may be accounted for when the view from the road is flat and uninteresting, or to confine the eye to the road by stately living walls of verdure, and leading to an object such as an obelisk, and this I take to be the main object sought by an avenue. The expression of an avenue is sombreness with dignity, affecting the spectator by its solemnity; hence we usually find avenues associated with monastic establishments, places of learning and burial, though, they are not unfrequent with manorial residences, as if to inspire visitors with a due sense of the importance of the proprietors or places. Except for promenades, walks, or drives for quiet recreation, or shady paths along a river side, for cemeteries, approaches to a mausoleum, and public institutions I do not think avenues worthy of imitation, as we suffer already by too much formality. Trees by the sides of roads form a very agreeable shade to pedestrians in summer, and are always agreeable to the eye; but the trees should be at such distances as to admit of light and air having free access between the several specimens, each having space to develop its head without coming into contact with its neighbour. It is a pity an injunction is not made to compel the planting of trees along the sides of public roads, at least those in the environs of towns.

In the disposition of trees we find little regard had to geological order by the planter. We not unfrequently find the Birch of the bog associated with the Spruce of Norway and Larch of the Alps, the Pinaster of the coast and Scotch Fir of the mountain with the Poplar and Willow of the river; and with a surface so varied as that of this country the geological order of planting is no doubt the best, for we have great variation of soil, and with water so abundant we have material wherewith to enable us to create landscapes of the greatest beauty. Hilly parts will display to the greatest advantage the towering Conifers. Rocky ground planted with them, in association with Gorse and other trees and shrubs, will enable the planter to produce an effect quite different, nevertheless in harmony, from that of the valley, where he will introduce trees of the plain—those that require rich deep soil; and near the margins of water trees requiring moist ground, such as Alder, Willow, &c., are the most appropriate.

It is sought very often to face Pines and other dark-foliaged evergreens with deciduous trees, remarkable for the rich tints of their foliage in autumn. There can be no objection to this mode of planting a hillside, where the Pines will occupy the higher ground, and all will be in harmony; but such an arrangement upon level ground is unsuitable, as the Pines in the background will be hidden by deciduous trees. I submit that evergreens intermingled with deciduous trees are undesirable. I am writing within a stone's throw of a plantation of Beech, another of Oak, and a third of Sycamore, all more or less interspersed with Conifers, the plantations being in open grove style—rather thick, but not so much so as to destroy the side branches of the deciduous trees. The Pines have tufts at the top, just as the deciduous trees close upon them, and these tufts of green have in spring and autumn a particularly fine effect when viewed at a distance or from an elevation; but I note that every year these dark tufts become less, the trees die or are uprooted by winds. The Spruces go first, having entirely disappeared from the Oak and Sycamore plantations; Silver Firs struggle hard for existence, and Scotch

Firs still more fiercely; but the Sycamores have completely overpowered them, and in a few years they will be gone, leaving nothing but deciduous trees. Planters may seek to produce combinations of evergreen with deciduous trees, but such combinations especially intermingled must not be looked upon as permanent, though if arranged so that the deciduous trees appear in the low or foreground with the evergreens at back they will go on for generations increasing in size, age, and beauty. Mixed up, as is the fashion, the deciduous trees will overpower the evergreens, driving them from the valley to their home in the hills, where they can tower in grandeur becoming those elevations which they so befittingly adorn.

The claim of Conifers is great (none greater than the Larch, which I shall have occasion to allude to again), and yet their use in ornamental gardening is carried to such a pitch of extravagance as to give a monotony of dark frowning forms which need, I think, considerable modification by the introduction of lighter-foliaged deciduous trees and shrubs.—G. ABBEY.

### HARDY ANNUALS FOR SPRING DECORATION.

HAVING observed that these "charming simple flowers" are considered worthy of attention, and having noticed a remark that they are only grown for spring decoration in large gardens, I desire to say that in at least one garden of moderate size they have long been employed extensively. In my endeavours to render the garden as attractive as possible, as well early in the spring as late in the summer, I have found autumn-sown annuals quite as indispensable as bedding Geraniums. These annuals, too, have always attracted more attention than the Geraniums, not only from those who might be regarded as having a special fancy for annual flowers, but from ordinary visitors, who could not resist expressing their admiration on seeing a garden in April and May bright with flowers, when their own beds were empty and cheerless.

Without further expatiating on the charms of hardy annuals, I will make the bold assertion that those who have not grown them by sowing the seed in autumn and flowering the plants in spring, or have not seen plants so grown by others, know nothing of the beauty of this class of garden flowers. The plan of sowing hardy annuals in the spring and leaving them thickly in lines or clumps to struggle out their brief existence as best they may, is not justice to them. As well may Lettuce seed be similarly sown, and the plants be treated in the same manner, and the practice be dignified as growing Lettuces. An individual plant of, say, *Silene pendula*, *Nemophila insignis*, or *Convolvulus minor*, requires quite as much room to perfect itself as does a Lettuce plant; yet while a square foot of ground is generally afforded to one plant of the latter, it is not by any means uncommon to find the same amount of space considered sufficient for fifty or a hundred plants of the former; and that is called growing annuals, and annuals are termed weeds, rubbish, transient fly-a-ways, and not deserving of a place in a garden. Judgment such as that is a libel on the annuals. The judges themselves are the criminals in denouncing the flowers which they first abused, for instead of having assisted them to grow they have prevented them from growing by the unnatural treatment to which they have been subjected.

It is the nature of hardy annuals to be sown in the autumn, as much as it is the nature of Wheat to be sown at that period. If Wheat is sown thickly late in the spring the crop is poor and the grain small, but if it is sown in the autumn thinly it produces massive heads of "golden grain." So with annuals; if the seed is sown thickly in the spring and the plants are untended they flower prematurely, and the flowers are puny and the plants miserable—quite unworthy of a place in the garden; but if the seed is sown in the autumn, and the plants are properly thinned and cared for, then is the result indeed different, for the plants instead of being puny become luxuriant, and their beauty instead of being transient is lasting—continuing often longer than is required, but always long enough to well reward for the rational cultural attention that has been bestowed on them.

I have sown seeds of *Convolvulus minor* in September—the rich dark variety known as tricolor—tended the plants through the winter, planted them in a rich and well-trenched bed in March, and they have commenced flowering in May, and have continued until October, most of the time presenting a glow of colour unequalled by any other bed of flowers of the same hue in the garden. That is an extreme case, and annuals are not usually required to flower nearly so long as that. The

beds are required for Geraniums, carpet bedding, or sub-tropical plants. The two last modes of decoration are now popular, and neither system can be commenced with until the first or second week in June, especially when *Alternantheras* must form a considerable part of the carpet-bedding arrangements. Beds of bare soil are endurable until May, but from the commencement of that month until the summer days and nights of June come in every day seems a week, so blank and dreary is the garden. Flowers you may find in fields and woods, in lanes and in hedgerows, on the mountain side and the streamlet's banks; but the flower garden excepting the *Daisies* on the lawn is flowerless. But it need not be so dreary, for throughout May it may be in its very brightest and most cheerful garb with annuals, and which are not only charming but accommodating, and will step out of the way just in time for the carpet bedders and subtropicals. Thus with the judicious use of annuals judiciously grown, a garden may be made to possess a double season of beauty, and with much less than a double outlay of cost and labour.

It is only right, however, to say that when autumn-sown annuals are grown some additional labour is incurred and must be provided if the plants are to be grown well, and if they cannot have justice done to them it is better not to attempt growing them at all. Yet when the labour is provided, and the beds are produced in good order, few can begrudge their cost, and fewer can ignore their beauty.

Who can inspect close pink masses of *Saponaria calabrica*, especially when surrounded with the white variety, the sprightly blue of *Nemophila insignis*, the richer hue of *Venus's Looking-glass*, the yellow of *Lasthenia californica* and *Limnanthes Douglasii*, and not admire them, to say nothing of those annuals of bolder growth—the *Clarkias*, *Viscarias*, *Larkspurs*, &c.? All these and many others are much finer when sown in autumn than when sown in spring.

This, however, is not the time for sowing hardy annuals. On the contrary, plants of *Silenes* and *Forget-me-nots* ought now to be 6 inches across, and those of the others should be well above ground. But if this is not the time for sowing the seed, it is the time for thinning the plants. Without proper and timely thinning, plants of hardy annuals cannot be expected to endure the winter's severity. It is the thinning-out of the plants that makes them hardy; if allowed to grow thickly together they become tender. A small solitary plant of *Groundsel* or any other indigenous weed will pass the winter uninjured, but a crowded group of these weeds made tender by the crowding cannot resist the severity of the weather. It is precisely the same with hardy annual flowers, which are hardy or tender according to the treatment that is given them. Every plant should be clear of its neighbour, then will its tissue become hardened and its habit be sturdy, enabling it to pass with safety our ordinary winters. Yet should the frost be extremely severe and no snow on the ground and plants, a little protection may be necessary, but the work of lightly laying over the beds dry tops of *Asparagus* (minus the seeds), or a few branches of evergreens is only the work of a few minutes, and will not be begrudged when success is attained.

Then how charming are hardy annuals when flowering in pots in the earliest days of spring! I cannot conceive, for instance, how plants of *Nemophila insignis* can be dispensed with for conservatory fringes, for baskets, stands, and other ornamental contrivances which gardeners are expected to furnish with flowers. Formal upright flowers we have in plenty, such as bulbs, *Azaleas*, *Cinerarias*, &c., but drooping plants are indispensable for the complete decoration of a conservatory or room, and these are afforded by trailing annuals. All the care these plants require is a frame in which to pass the winter, and a shelf near the glass to assist them in unfolding their flowers in the spring. With this little care and copious supplies of manure water plants are produced which are totally distinct from all surrounding them, and which surprise those seeing them for the first time, not only by their inherent beauty, but by their lasting properties.

Because I have seen hardy annuals so greatly admired in the spring, both in pots and in beds, I have always endeavoured to provide them; and because their culture is within the means of almost everyone having a garden that I say a word in favour of these "charming simple flowers."—A NORTHERN GARDENER.

### DIOSPYROS KAKI.

THE readers of the Journal who were thinking of investing half a guinea in the purchase of a small specimen of this plant

have reason to thank Mr. Wilson for giving his experience, and will probably withhold their orders until they hear a better account from other quarters. As the plant, according to the "Cottage Gardener's Dictionary," was introduced into this country as far back as 1789, and is mentioned by London as a greenhouse fruit tree, it might be assumed that if the fruit were worth having it would long before this have been generally cultivated; and had Mr. Wilson simply pronounced the fruit inferior to our ordinary English fruits I should not have troubled you with this letter, but his report is so very unfavourable that I must express a doubt whether this "Pear tree of Jove" in some of its varieties may not behave better.

A letter from Japan informed me that the Kaki was the best fruit there. Margary in his Journal mentions the abundance of the tree in China, though it is possible that the trees were wild. Perhaps Mr. Wilson has overlooked the statement made by Don, that the fruit of every variety of *Diospyros*, and notably of the Virginian tree, must be allowed to blet like the Medlar, and I have understood it is all the better for frost. If Mr. Wilson has any fruit left, perhaps he will kindly try whether keeping it diminishes its austerity.—G. S.

### OUR OLD ROSES.

WHAT changes have come over the queen of our gardens! Interesting and instructive as "Election of Roses" may be to many of your readers, how few of us can keep pace with the times. I would be glad to enter the arena, but cannot for ever be discarding and adding Alfred Colombes and Marie Baumanns to the limited stock. In days long past with what delight we used to tend such Roses as Rivers's George IV., Russelliana, Madame Campan, Las Cassas, Great Western, Madame Desprez, and we thought when we procured Giant of Battles we had arrived at the end of the chapter. The last-named Rose was expected to have a very prominent place as a Rose for bedding purposes, but having such a tendency to mildew had to be discarded. Coupe d'Hébé was thought to be the model of a Rose, and Lamarque used to be very highly esteemed, and with some still holds its own. Such Roses as Baronne Piévest and Colonel Rougemont we cannot do away with; and we used to think that Paul Perras, Charles Lawson, Princess Matilda, and the like, would never grow old. We retain them still, and shall not give them up. Our affections still cling to that grand old Rose the Provence Cabbage and its compeer the old, old Moss, a staunch old friend. I wish the Bath White and Timewell's Moss would grow as well. Charles Duval still retains his merit in my estimation; and the Crested Provence Rose is one of the most lovely Roses in cultivation.

It is grievous to see how low in the scale that much-lauded Rose has sunk—I mean Gloire de Dijon. I shall never forget the praises lavished upon it when it first made its appearance among us. I used to think we should never need another Rose introducing; but the light of other days has faded, but still "old Glory" holds a place in our affections, and is generally esteemed. In our youthful days we used to have a Rose called Smith's Yellow Noisette; it was a grand achievement to cut a few blooms in February and March of this variety from the forcing house, but we see nothing of this Rose now. My ideas may be vague, but I have a great liking for the double Persian yellow Madame Angelina, she is so charming in bud; also for Bourbon Queen, Joséphine Matton, Devoniensis, Niphetos, Elize Sauvage, and Goubault.

Jean Desprez and Ophirie are fine for borders. We were to have something very superior in Cloth of Gold and Isabella Gray, but they are too unmanageable. Of course the Marshal has his proper place. I still cling to the old Damask known as the York and Lancaster—beautiful in bud and that is all.—Rosa.

### CHAPTERS ON INSECTS FOR GARDENERS.

No. 13.

THE genus *Phylloxera*, represented by such species as *P. coccinea*, *vastatrix*, and *quercus*, presents such strange anomalies that our entomological leaders are puzzled as to its place in this order. Like the scale insects, the females are oviparous, but the parents do not die off to furnish a protective coating for the young. In several instances broods in various stages of growth reside within galls formed on the roots or branches of the plants they attack, the *Phylloxera* resembling the Aphides, in their succession of summer broods consisting only of females. Excellent, therefore, as are some of the remedies proposed, they have this awkward circumstance

against them, that owing to the secluded habits of the majority of the *Phylloxera*, the killing agent cannot be placed near enough to them. As to their rapid multiplication, on the Oak leaves during July or August there may be observed, where the insects occur, a dozen or more of females upon a single leaf, each surrounded by her batch of more than a hundred eggs, regularly arranged in circles. Some very startling statements have been published about these *Phylloxera* by the French naturalists, and not all of these have been verified as yet by sufficient observations. But it seems pretty well ascertained that the Vine-eaters, under certain conditions of their life, migrate to the Oak, and the reverse operation also occurs. Then the root-infesting *Phylloxera*, which are, for many generations, entirely subterranean in habit, are continued through a limited number of years by wingless females, until they die out, new colonies of the *Phylloxera* being propagated by the winged specimens bred from the leaves. And if we could credit M. Balbiani, that some females only deposit a single egg at the period when the winged development occurs (though another naturalist deems this a pupa), we should deem the

Fig. 66.—*Phylloxera vastatrix*.

Female specimens and their eggs. *a*, antennae; *b*, horns or suckers; *c*, egg plainly visible in the body of the insect; *f*, winged form of the insect. All magnified.

*Phylloxera* pre-eminent amongst their brethren on account of their peculiarities.

We come next to the Coccidæ or Scale Insects, which have been so named from the singular structure of the females, which are invariably devoid of wings. It is so ordered that by their habit they furnish a remarkable illustration of "life in death." The scale, attached to some trunk or branch, and which differs much in size in different species, a large example being that discoverable on the Vine, is the carcase of the parent insect, from which, by an odd transformation, disappear all trace of segments, legs, antennae, and head, leaving only the shield-like convex ridge of the upper surface of the body, on raising which we see a white or yellowish substance. In this are enclosed the eggs, which sometimes hatch out speedily, sometimes continue unchanged from autumn until spring. Whether the young larvæ are partly nourished as well as protected by the relics of their diseased parent is not certain. The newly-hatched Coccoi, however, soon begin to suck the juices of the plant by the aid of the rostrum or "beak," but though they are occasionally written of as active, their activity is of a very moderate kind. From the extremity of the body spring two longish tails or bristles, which perhaps serve as balancers, or they may be connected with the breathing apparatus; but they do not abide through the whole of the larval life.

In the case of the Coccoi that are about to pass the colder months of the year as larvæ, towards the end of the summer it will be found that they have distributed themselves on the younger shoots, finally quitting the vicinity of their parent, and rousing to renewed activity in April. Should these be left undisturbed, ere long we notice that some of them continue to increase in size, while the others cease to grow. The females, indeed, pass, without any marked gradation, from the state of larva to that of imago, and, until they are impregnated, still draw up the sap; the males, ceasing to feed, become pupæ, and emerge as winged insects. They again exhibit the bristly adornments perceivable in the larvæ, and the pair of delicate wings, sometimes of very gaudy tints, cross each other. Though well able to fly, locomotion is more frequently performed by them in a series of hops or skips. This description may be taken as applicable to the yearly round of life in most of the outdoor Coccoi, such as that haunting the Sycamore, or that feeding upon our Hawthorn hedges. The latter species has, I think, become more numerous of late, though scarcely capable of effecting any important injury to this shrub, which has so many more dangerous foes. Under glass, where vari-

ous species of the scale insects love to congregate, disturbing the horticulturist's equanimity, and forcing him to infect the atmosphere with unpleasant odours, their proceedings cannot be counted upon with certainty. Occasionally there would seem to be two broods in a season.

So deadly is the influence exerted upon some plants by scale, apparently out of proportion to the exhaustive effect of their mere sucking, that theories have been suggested by speculative persons giving other explanations. It has been thought that the Coccæ may give out some hurtful secretion, or that by their hold upon the young twigs they thwart the natural growth and impede respiration or assimilation. Small consolation is it to be told of the benefits bestowed upon us by some of the Coccidæ; and even as no one, Shakespeare being witness, can hold fire in hand by thinking of the Arctic regions, so is it impossible to excuse the scale, which, if permitted, would swarm over our choicest plants in the hothouse or pinery, for the sake of its valuable brethren, which, in sunnier lands, yield that useful product lac, or the splendid colour which is obtainable from cochineal. Some years ago I read particulars of a scheme for the introduction to this country of the Mexican species (*Coccus Cacti*), which, it was supposed, under skilful management, might prove a new source of national revenue. As no recent details have been published, I presume the matter has been dropped.

That choice plant the Pine Apple, and the favourite exotic Orange Tree, have each their enemy of the Coccus tribe, though both these pests are occasionally found on other plants or trees; the Pine Apple Scale (*Aspidiotus bromeliæ*), clustering sometimes on Malvaceous plants. The Vine Scale (*Lecanium vitis*) is so conspicuous where it occurs that its destruction by hand-picking is comparatively easy, and it only affects Vines under cover. The Turtle Scale (*L. testudo*) is one of the commonest, frequenting our conservatories, escaping notice often when it has placed itself on the leaves of plants. The Coccidæ are not without their insect parasites, some of the four-winged flies belonging to the family of the Chalcidæ deposit eggs amongst them, and they have doubtless other parasites as yet unrecognised by us.—J. R. S. C.

### THE NATIONAL AURICULA SOCIETY.

My attention has been directed to the paragraph at page 425 by "*D., Deal*," in your last week's issue—viz., "The National Auricula Society will not hold its Show in London," and I am to request your permission to say this paragraph is quite inaccurate and can only mislead.

Not only is there no refusal on the part of the Society to hold the Show in London, but the suggestion to hold it comes from the Honorary Secretary and other of its principal members; and every step taken and to be taken has been, and will be, in full accord with Mr. Horner's mind. Had "*D., Deal*," said the London exhibition of the National Auricula Society is not proposed to supersede the exhibition of the same Society at Manchester he would have recorded a fact, and one rejoicing to the hearts of florists.

It has been arranged by the Crystal Palace Company to hold the National Auricula Exhibition for 1877 at the Palace on Tuesday, April 24th.—E. S. DOWELL, *Hon. Sec. pro tem*, London Division, National Auricula Society.

### BRIXTON HILL CHRYSANTHEMUM SHOW.

CHRYSANTHEMUMS are the princes of autumn flowers, and if we want to see them in fullest beauty we must visit the metropolitan shows of them. The plants at a few shows have been noticed—the tall robust specimens at the Temple and the Crystal Palace; Mr. Turner's upright-trained plants, so fine for the sizes of their pots; Messrs. Veitch's sturdy specimens and splendid blooms; and Messrs. E. G. Henderson's luxuriant plants at South Kensington. But distinct from all these were many plants at Brixton which were artistically trained, proving, as so many other similar exhibitions have proved, the great tractability of the Chrysanthemum when handled by skilful cultivators.

The Brixton, Streatham, and Clapham Horticultural Society was established nearly twenty years ago for "promoting the superior cultivation of plants, fruit, and vegetables by means of exhibitions, at which all members may enter into friendly competition." The district, being salubrious, has been chosen by many gentlemen for their residences, gardeners are consequently numerous, and horticultural exhibitions have improved yearly. The last was held in the Holy Trinity schoolroom on the 17th and 18th inst., and was an undoubted success. The spacious

room was not only crowded with Chrysanthemums and other flowers, fruit, and vegetables, but the attendance of visitors, especially during the evenings when the room was well lighted, was enormous; the dense crowd, in fact, demanded a building of at least three times the size to have enabled them to enjoy the Exhibition in comfort. Neither was it a concourse of mere sightseers visiting the Show for momentary gratification, but the majority were evidently earnest workers in the floricultural hive, and were diligent in jotting down names and "wrinkles," such as might be of service to them individually. It was gratifying to notice this assiduity on the part of so many in adding to their stores of knowledge, and was a complete answer to the question—half cynical, half sceptical, which one is often compelled to hear—"Of what use are flower shows?"

Another episode of this Show may be noted, which is as gratifying as it is rare. When noticing the Chrysanthemums in the Temple Gardens we remarked on the power of a Rose show in subduing a prizefighter and transforming him into a rosarian, but at the Brixton Show an ex-pugilist of more than ordinary renown vanquished all comers in the premier class for cut blooms, the conqueror of J. C. Heenan having proved victorious with twenty-four splendid blooms, staged by his gardener, Mr. Lee. Mr. King, the "Tom King" of history, is a gentleman highly esteemed in his neighbourhood, a good supporter of the Society, and a great lover of and an earnest cultivator of plants. The peaceful pursuit of horticulture is now followed by one who once in another and widely different sphere was "earnest for his country's fame." We have only to say now that Mr. King's blooms were veritable champions, or, as a bystander appropriately described them, "regular stunners." Mr. King was also first in the "maiden class," this having been his first time of exhibiting.

The most noteworthy plants in the Exhibition were unquestionably the six large-flowered specimens staged by Mr. Hall, gardener to W. Stevens, Esq., Lower Tulse Hill, in Class 1, and the six pyramid Pompons in Class 3 belonging to the Rev. W. Arthur, Clapham Common, and grown and exhibited by his gardener, Mr. Harding. The plants in these two collections attracted the lion's share of notice as being admirable examples of skilful cultivation. Mr. Hall's specimens were by no means the largest in the room, but for health, vigour, symmetry, and finish they were such plants as many aim to produce and but few succeed in producing. They were in 11½-inch pots, the plants being flattened semiglobes 3 to 3½ feet in diameter, each plant containing fifty to seventy perfect blooms, each being set in its right place and surrounded with foliage, the leaves being continued to the bases of the stems and the centres of the plants. These plants were so tied that the blooms were not more than 18 inches from the surfaces of the pots, and the stakes were scarcely visible. This almost perfect half-dozen plants comprised Mrs. George Rundle, Prince of Wales, George Glenny, Faust, Mr. Brunlees, and Lady Hardinge. Mr. Harding's Pompons consisted of the three Cedo Nullis, lilac, white, and yellow; Bob, Madame Martha, and Antonius. All of these were exceedingly fine, especially Bob and Madame Martha, probably the best dark and the best white varieties in cultivation. The plants were in 8-inch pots, and were about 2½ feet in diameter at the surfaces of the pots, and were about 3½ feet high—perfect cones, each terminating with a point, and not a stake was visible. Each plant had a clear single stem; and the flowers, which were fine, having been carefully thinned, covered every part of the cones, the number of flowers on the largest plant probably being three to four hundred. The second prize in this class went to Mr. Livermore. Mr. Harding also secured the first prize for three plants "not pyramids," Mr. Betts being placed second. These were of semiglobular form, about 2½ feet in diameter, and not far exceeding a foot in height from the surface of the pots. The varieties were Madame Martha, Bob, and Mr. Astie. Mr. Harding also secured the second prize in the specimen class with a handsome pyramid of Madame Martha; Mr. Livermore, gardener to F. Webb, Esq., Streatham Hill, winning with an admirable specimen of Mrs. G. Rundle, 4 feet in diameter, and carrying seventy blooms; Mr. Hall securing the third place, also with a large-flowered variety.

Mr. Harding's plants are particularised in order to dispel a very prevalent yet erroneous idea, that such specimens cannot be exhibited except by large growers—that is, by those having a large number of plants to choose from. We are able to vouch for the fact that Mr. Harding commenced the season with only eleven plants, and ten of them are those above noticed. The garden in his charge is small, the houses being also miniature structures, therefore he wisely limited his plants to under a dozen, and growing them well instead of including a great number of varieties and growing them indifferently. Two useful deductions are derivable from Mr. Harding's success—the necessity for properly estimating conveniences and not attempting too much, and that a few plants well grown are more creditable and satisfying than a large number of what Mr. Luckhurst designates "miserable starvelings." Mr. Weston, gardener to D. Martineau, Esq., Clapham Park, well known as an experienced and

skilful grower, was awarded the second prize in Class 1 for healthy, compact, medium-sized specimens 2 to 3 feet across; the third prize going to Mr. Young, gardener to T. Hicks, Esq., Streatham Hill, for plants 4 feet in diameter, but rather widely staked-out. Mr. Harrington staged plants too late for competition, otherwise they would have secured a share of the honours, as they did of public approval.

In the class for three large-flowered specimens excellent plants were staged. Mr. Young securing the first place with well-shaped plants 4 feet in diameter of Mrs. Dixon, Mrs. G. Rundle, and Guernsey Nugget; Mr. Hall was second with smaller and more compact specimens of Lady Hardinge, Venus, and Mrs. Haliburton; and Mr. Livermore third, also with good plants. In this class the Judges awarded the palm to size of plants; in Class 1 to symmetry and compactness. Mr. Hall's Mrs. Haliburton was a model of good culture, almost every bloom being perfect. For six dwarf Pompons Mr. Weston won with "pau-cakes" 3 feet in diameter of Aglaia, Cedo Nulli, Golden Cedo Nulli, Regulus, La Sultana, and Antonius, but the plants had been too recently tied, the flowers "looking sideways." Mr. Hall had the second place with smaller and more naturally trained plants. Standards were not good, the only award going to Mr. Livermore for plants with stems  $3\frac{1}{2}$  feet high, and rather loose heads 18 inches in diameter.

In the classes for cut blooms the display was extensive. The boxes extended to a length of about 100 feet, and the effect of the many-coloured flowers was very imposing. The blooms were not remarkable for their prodigious size, probably on account of the earliest sorts (which are the largest) having been past their best, yet the quality was good. In the class for twenty-four blooms the prizes were awarded to Mr. Lee, gardener to T. King, Esq., Lower Tulse Hill; Mr. Ottaway, gardener to T. Hepburn, Esq., Clapham Common, who were placed first and second respectively; Mr. Howes, gardener to Mr. Butler, Tulse Hill, and Mr. Livermore were equal third. For twelve blooms the honours went to Mr. Crisp, Mr. Ottaway, and Mr. Holmes in the order named; and in the class for six blooms where ten competed the winners were in the same places, substituting Mr. Howes for Mr. Holmes as the third prizewinner. The best blooms in these classes were Mrs. Heale (finest of all), Princess Alexandra, Empress of India, Jardin des Plantes, Prince of Wales, Prince Alfred, Mr. Gladstone, Cherub, Mr. Brullees, John Salter, Hero of Stoke Newington, and White Globe. The above were the largest. Smaller but equally good were Eve (very lovely), Mrs. G. Rundle, Lady Slade, George Glenny, Barbara, Miss Hope, White Beverley, Venus, Baron Beust, and Aurea multiflora, Mrs. Dixon, and Fingal. Mr. Livermore and Mr. Ottaway were the winners with large Anemone-flowered varieties. The best blooms were Empress, Louis Bonamy, Prince of Anemones, Acquisition, Fleur de Maie, Gluck, King of Anemones, and Mrs. Pethers. The same exhibitors, with Mr. Wells, were successful with cut blooms of Anemone Pompons, who each staged attractive collections, which were honoured with a large share of appreciation by the visitors, who were so intent on "taking names" that the stands could only with difficulty be inspected. The best varieties in this section were Regulus, Marie Stuart, Fire King, Perle, Mrs. Wyness, Calliope, Madame Montels, Antonius, Mr. Astie, Sidonia, Dick Turpin, and Madame Challenge.

Besides the Chrysanthemums, prizes were offered for sundry other plants, also for fruit and vegetables. Mr. Legg, gardener to S. Hall, Esq., was a successful exhibitor of Orchids—good *Calanthes* and *Odontoglossum Roezlii*; also Mr. Weston, who staged *Cymbidium Mastersii*, *Maxillaria picta*, *Sophronitis grandiflora*, and *Cypripedium insigne*. In fine-foliaged plants Mr. Legg won in the single specimen class with *Nepenthes Rafflesiana*, having sixteen pitchers. Mr. Hall was the winner in the class for four plants, and staged bright and healthy examples of *Livistonia australis*, *Dracena Cooperii*, *Anacassa sativa variegata*, and *Alcassia metallica*. Others successful in these classes were Mr. Wells and Mr. Wright, gardener to M. Voss, Esq., Streatham Hill. Good Ferns in 10 inch pots were staged by Mr. Young; Mr. Davey, gardener to B. Drew, Esq., Streatham; and Mr. Crisp, who were placed in the order of their names. Ferns in 6 inch pots were numerous and excellent, and Mr. Wright; Mr. Stapley, gardener to W. H. Walsley, Esq., Clapham Park; and Mr. Cherry, gardener to R. Slee, Esq., Streatham Hill, were well deserving of their prizes. Primulas were numerous, and the plants generally were very healthy and fine, but had not attained to their best flowering state. The awards for eight plants went to Mr. Fulbrook, gardener to B. Baker, Esq.; Mr. Halliday, gardener to J. Olney, Esq., Balham; and Mr. Hall. Classes were provided also for berry-bearing plants, sweet-scented plants, and table decorations, in all of which there was competition.

Fruit was well exhibited. Mr. Davey, gardener to B. Drew, Esq., Streatham, was placed first in the class for four distinct dishes with a Pine Apple, good Lady Downe's Grapes, Chant-montel Pears, and Duncan Apples, the remaining prizes going to Mr. Rockell, gardener to F. Falconer, Esq., Clapham Park,

and Mr. Cherry. For four dishes of Pears Mr. Brooker, gardener to J. Kolle, Esq., Tulse Hill, Mr. Hall, and Mr. Cocks, gardener to G. T. Cundell, Esq., were placed in the order of their names. The best dishes included Marie Louise, Beurré Diel, Beurré d'Aremberg, Beurré Bosc, Beurré Bachelier, and Chaumontel. The best kitchen Apples were Blenheim Pippin, Emperor Alexander, and Cox's Wax Pippin; and the best dessert Apples were Ribston Pippin, Cox's Orange Pippin, and Cockle's Pippin. Of Grapes there was a very creditable display. For three bunches of Black Grapes Mr. Davey won with Lady Downe's, fine in appearance and good in quality. Mr. Cherry, gardener to R. Slee, Esq., Streatham, was second with Black Hamburgs of superior quality, but rather deficient in colour; equal third prizes going to Mr. Ottaway for fine-looking Alicantes but deficient in flavour, and Mr. Davey for full and attractive bunches of Black Prince. Messrs. Rockell, Cocks, and Cherry were successful in the Muscat class, and Mr. Davey was "all alone in his glory" in the class for Pine Apples.

Very good vegetables were exhibited. In the class for any number of varieties Mr. Livermore was placed first with a collection suggestive of a well-stocked garden. Almost every vegetable in season was represented, from Chinese Yams to Tomatoes, nearly every dish being of superior quality. Mr. Wright had the second place with a contribution of nearly equal merit. For eight dishes Mr. Davey was placed first, owing principally to his good Cucumbers; Mr. Harding was second, Tomatoes and Vegetable Marrows placing him ahead of Mr. Horsham, who had the third prize with produce which was generally overgrown. For Cucumbers Mr. Cherry won with The Hero; Mr. Young and Mr. Davey following with Telegraph.

Such is a sketch of this excellent Show. The Society started in a small way, but by unity and perseverance has achieved a creditable position. It has the advantage of a practical committee, and an active and courteous secretary in Mr. Goldsmith.

#### WIMBLEDON HORTICULTURAL SOCIETY.

This flourishing Society held a show of Chrysanthemums, fruit, and table plants at the Lecture Hall on the 15th and 16th, and some praiseworthy collections were brought together. The splendid bank of plants, 30 feet by 10, staged by Mr. Lyne, gardener to A. Schlusser, Esq., Belvedere House, Wimbledon, was the admiration of everyone. Some Sugar Canes, forming a background, sent by Mr. Ollerhead, gardener to Lady Peek, made up a very attractive group. Mr. Smith staged an effective group of twelve miscellaneous plants, which contained amongst them *Paullinia thalictrofolia*, *Dracena metallica*, *Croton interruptum*, and *Yucca aloifolia variegata*, all well grown and beautifully coloured; two plants—*Croton variegatum* and *C. Johannis*—were especially well finished. Mr. Bridger, gardener to F. B. Thomas, Esq., East Hill House, Wimbledon, staged a good collection; and collections of fine-foliage plants were also sent by Mr. Ollerhead, Mr. Lyne, Mr. Stratton, gardener to Miss Forbes; and Messrs. Thompson, nurserymen, of Wimbledon. Mr. Bridger and Mr. Elliott exhibited collections of Scarlet Geraniums, which, for the season of the year, were particularly fine. The principal exhibitors of cut blooms of Chrysanthemums were Messrs. Whittaker, Bentley, and Burden. Mr. Appleby, the Secretary, also staged a very creditable collection. Fruit was shown in large quantities by Messrs. Lyne, Fanning, Ansell, Tucker, and Chapman. Mr. Lyne's collection comprised twenty-two dishes, the whole being of superior quality.—M.

#### DARTFORD CHRYSANTHEMUM ASSOCIATION.

The sixth annual Exhibition of this Association was held in the Victoria Assembly Rooms, Dartford, on November 15th and 16th, and both specimen plants and cut blooms were shown in excellent style. The amateurs' productions were especially superior, notably the collection of Mr. H. R. Hards, which contained fine examples of Empress of India, St. Patrick, Isabella Bott, Prince Alfred, Golden Queen of England, Lady Hardinge, G. Glenny, and Mrs. G. Rundle. Mr. C. White, another amateur, had good examples of G. Glenny, Mrs. Rundle, and Gloria Mundi. The following also obtained first prizes as amateurs: Messrs. Evitt, Lanyon, and Southernden. Among gardeners: E. Ryder, Dancer, Carter, Brown, Pendred, and Shaw were successful. The magnificent plant of Mrs. G. Rundle shown by Mr. Dancer, gardener to G. H. W. Porteus, Esq., deserves a word of praise. It was 4 to 5 feet through, trained in a somewhat flat bush-like form, and had from 150 to 200 good blooms. The Society is to be congratulated on the success achieved, for the arrangements of the Show were well carried out by Mr. Shelton, the Hon. Sec., and his able colleagues.—J.

#### VERONICA BLUE GEM.

THANKS to someone who on page 406 of our Journal has noted Veronica Blue Gem as a valuable plant where cut flowers are in demand. The plant I have under the above name

appears to be a diminutive species of *Veronica speciosa*, and is hardy in some places in the north. It is deserving a place in all collections. Too much cannot be said in its favour for either in or out door decoration. It is now in full bloom both in and out doors; its small bright foliage and lovely flowers are beautiful in the frost and snow that now surrounds the plants. It thrives well in any ordinary garden soil; it is readily increased by cuttings or division.—NORTHEMAN.

### NOTES AND GLEANINGS.

WE understand that a CONFERENCE OF ROSE EXHIBITORS AND ROSE GROWERS will be held on Thursday, December 7th, at the Horticultural Clubhouse, 3 and 4, Adelphi Terrace, at 2 P.M., for the purpose of devising some satisfactory arrangement as to the future of Rose shows, &c. Amongst the subjects to be discussed will be the formation of a National Rose Society or Club, an idea which was started at the last Hereford Rose Show; the abolition of two-day Rose shows; and the revival of the National Rose Show, which was merged some years ago in that of the Royal Horticultural Society, and has fallen through. Already many of the leading rosarians, both amateurs and professional, have signified their intention of being present, and we are requested to state that circulars will be sent to all Rose exhibitors as far as known; but should any be inadvertently passed over, it is hoped that they will consider this notice as sufficient. There will be a dinner after the conference is over.

— IN another column will be found a report of the BRITON CHRYSAETHUM SHOW, in which a noted ex-pugilist proved a veritable champion. Other Chrysaethum shows have recently been held—at Woolwich, Hackney, Lambeth, Stratford, &c.—proving that the Chrysaethum is a great favourite with Londoners, and deservedly so, for no flower gives better returns to the cultivator. None braves metropolitan smoke so well, and penetrates November fogs with flowers of equal purity and beauty. Excellent plants and superior blooms have been staged at all the exhibitions, and young growers are vying with the "old hands" as earnest and skilful cultivators.

— A CORRESPONDENT, "J. P.," informs us that Williams' SILVER BALL TURNIP is a variety of the greatest excellence. He states that he sowed seed of it, also of three other sorts, at the same time, and Silver Ball was not only the earliest, but it continued in use long after the others had run to seed. He says also that the cook prefers it to all other sorts, and he intends to grow it exclusively in the future.

— MR. D. LUMSDEN, Bloxholm, writes to us that on looking over his POTATOES the late sorts, such as Paterson's Victoria, Dunbar Regents, &c., are found to be extensively diseased; indeed they are as bad as ever they have been seen in that neighbourhood; but that all the early garden varieties have escaped the disease.

— "OBSERVER," writing further on GRAPE-GROWING, states that all the four Vines mentioned on page 423 were stocks, and that he ought to have written "The influence of one stock on another," instead of "The influence of the stock upon the scion."

— IN reference to STRAWBERRIES IN NOVEMBER Mr. Frisby of Blankney writes that he has had plants sent to him under the name of Viscomtesse Héricart de Thury which proved identical with the sort he grows as Garibaldi. He considers this the best forcing Strawberry, and grows from twelve to thirteen hundred pots of it. In April the early-forced plants are planted in rich soil, and always produce good crops of fruit in the autumn, and he has now plants in full flower and fruit. A correspondent in Lincolnshire also alludes to the valuable autumn crops of Strawberries which he has seen at Blankney, and states that Garibaldi and Viscomtesse Héricart de Thury are considered in that district as being synonymous. Mr. Lumsden of Bloxholm is also of that opinion.

— MR. HALLIDAY, late gardener to Admiral Popeham, Carden, Forfarshire, has been appointed head gardener to Mrs. Wemyss, Wemyss Castle, Fifeshire. Mr. Judd, who has recently been appointed gardener at Warwick Castle, was gardener at Hawkstone, not Oxtou, as previously announced.

— WE learn that a NATIONAL AURICULA SHOW will be held at the Crystal Palace on April 24th. The Crystal Palace Company have offered £10, and other contributions of £5 besides small sums are already promised towards the prize list. The

northern growers are willing to co-operate with their southern friends, and an exhibition of more than ordinary magnitude is anticipated. F. Whitbourne, Esq., Loxford Hall, is appointed President; Mr. Turner, Slough, Treasurer; and Mr. E. S. Dodwell, Larkhall Rise, Clapham, Honorary Secretary of the Society.

— THERE is now flowering in the Crystal Palace for the second time this season an old but useful greenhouse plant which is not now in general cultivation—*CESTRUM AURANTIACUM*. This plant, which is allied to *Habrothamnus*, is not only suitable for walls and pillars, but flowers freely in quite a dwarf state—that is, cuttings struck in the spring and grown through the summer in the open air, having their pots plunged in ashes, become useful decorative plants in the autumn. We have recently seen plants in 5-inch pots flowering freely, and their drooping racemes of orange-coloured flowers were much prized. In the Alhambra Court at the Crystal Palace a fine plant of *Aralia papyrifera* is flowering. The leaves of this plant are fully 3 feet in diameter. In the same Court the Dragon's-blood Tree and other *Dracenas* are in superior condition, and this part of the Palace is worthy of a visit. The cleanliness and general good health of the plants and trees in the immense structure afford evidence that they are well cultivated and cared for.

— WE have received from Mr. Bennett of Rangemore a sample of GROS COLMAN GRAPES. The berries were closely set, and not one of them measured less than 3½ inches in circumference; they were also tolerably well coloured, but not perfectly black. Although this Grape is not esteemed by Mr. Bass, and is being supplanted at Rangemore with other varieties of better flavour, yet the Grapes sent were juicy and refreshing, and were, we think, superior to any of the same kind which we have previously tasted. This is a noble-looking Grape, and some cultivators find that when it is grown in a tolerably high temperature and is ripened early, that its quality is much better than when the Vine is grown in a cool temperature. Mr. Wildsmith speaks well of Gros Colman, and has recently exhibited it excellently well at South Kensington.

— A "DURHAM AMATEUR" states that he has PRESERVED TEA AND OTHER TENDER ROSES annually by digging them up in November and laying them in by their heels in a part of the garden where he could cover their tops with litter in severe weather. He does not recommend a south border for thus storing them, as in such a position the buds are apt to commence growth too early in the spring. A few dozens of Roses can be laid in a small plot of ground with a little expenditure of labour. Before adopting this plan he annually lost some much-valued Roses, but now he has bushes which he has thus preserved for several years, and such Roses flower freely during the summer and autumn months. He states that the frequent removals have induced the trees to form bushy fibrous roots very different to the ordinary roots of Roses which are left to grow year after year without being removed.

— THE COLORADO POTATO BEETLE.—Information has been received from the German authorities, conveyed to Her Majesty's Minister at Berlin, on the capture of the insect on board ships at Bremen, and also with regard to their introduction into Sweden. The insect not only moves by flying, and by navigating, so to speak, smooth water, but also travels on common vehicles, railway carriages, and platforms, on decks of vessels, &c., especially during the months of August and September. In localities fully invaded, the beetles may be seen creeping on side walks, bridges, and wharves, crawling up buildings, penetrating houses and dwellings, finding their way into boats and vessels, and being found alive after a long sojourn in situations where there would seem to exist no chance for them to find any subsistence. If, however, the absolute repelling of the invader is unfortunately beyond reach, the extent of the disaster is fortunately in a very great measure under control, involving, of course, care and expense. The remedies are—1, Searching for and crushing every Potato beetle wherever found. 2, Frequent visits to the Potato fields, and searching for the eggs deposited on the under side of the leaves of the Potato vine; and 3, Watching for the presence of the larvæ on the buds and on the leaves of the plant, in order to destroy them by means of Paris green, the only substance yet discovered to be effectually operative.—(*Daily Telegraph*.)

— ANCIENT TOUGHENED GLASS.—In a "Book of Curiosities" we read—"There was an artificer in Rome who made vessels of glass of so tenacious a temper that they were as

little liable to be broken as those that are made of gold and silver. When, therefore, he had made a vial of the purer sort and such as he thought a present worthy of Cæsar alone he was admitted into the presence of their then Emperor Tiberius. The gift was praised, the skilful hand of the artist applauded, and the donation of the giver accepted. The artist, that he might enhance the wonder of the spectators and promote himself yet further in the favour of the Emperor, desired the vial out of Cæsar's hand, and threw it with such force against the floor that the most solid metal would have received some damage or bruise thereby. Cæsar was not only amazed, but affrighted with the act: but the artist, taking up the vial from the ground (which was not broken, but only bruised together, as if the substance of the glass had put on the temperature of brass), drew out an instrument from his bosom and beat it out to its former figure. This done, he imagined that he had conquered the world, as believing that he had merited an acquaintance with Cæsar and raised the admiration of all the beholders; but it fell out otherwise, for the Emperor inquired if any other person besides himself was privy to the like tempering of glass. When he had told him 'No' he commanded his attendants to strike off his head, saying that should this artifice come once to be known, gold and silver would be of as little value as the dirt in the street. Long after this—viz., in 1610, we read that among other rare presents then sent from Persia to the King of Spain were six mirrors of malleable glass so exquisitely tempered that they could not be broken."

— THE HOT-WATER APPARATUS fixed in the Arctic ship "Discovery," by Mr. Henry Ormson, King's Road, Chelsea, is stated to have proved highly successful.

### ROSES IN SMALL GARDENS.

I CANNOT agree with "E. M., Croydon," in his strictures on Rose-growing. They seem to me to be only applicable to those who have spacious grounds, and therefore can indulge in giving each Rose plenty of space for "its voracious appetite." But he can know little of cottage gardens, or even of small villas, when he condemns the owners for growing Roses in the "midst of a crowd of other flowers." The small plots of ground available for gardens preclude the possibility of his advice being taken, unless, indeed, the plots are to be given up to the cultivation of one or two Roses, and, except for their few weeks of blooming, the owners are content to have their gardens a desert.

I quite agree with "E. M." that if Rose nurserymen would, with their Roses, send printed suggestions as to planting, &c., it would be a benefit to those who could profit by the advice; but permanent labels would only be valuable to a rosarian, not to an ordinary grower of flowers or a cottager.—R. S.

### REPORT OF THE BRISBANE BOTANIC GARDEN.

MR. WALTER HILL, Colonial Botanist and Director of the Garden, gives highly satisfactory details of its progress. We give a few brief extracts:—

The principal plants that have flowered or borne fruit during the past season for the first time are—*Enkianthus quinqueflorus*, *Moringa pterosperma*, *Rhopala magnifica*, *Toxicophlæa spectabilis*, *Phalanopsis Schilleriana*, *Vanda Hookeri*, *Cataldozamia McLeayi* (eleven years old), *Raphia Raffia*, *Areca alba*, *Chamærops excelsa*, &c.

During the past year 114,487 cuttings, 21,884 roots and bulbs, 25,089 plants, and 74 lbs. 10 ozs., together with 1065 packets of seeds have been distributed amongst 806 public and private establishments.

It is worthy of remark, and as a proof of the growing disposition exhibited for the cultivation of useful tropical and subtropical plants, that by far the larger proportion of these are plants of economic and commercial value, many of them introduced to this colony through the means of this establishment.

A number of indigenous Grasses have been tested with satisfactory results. Amongst them are:—

*Cynodon dactylon* (Couch or Indian Doob Grass), which is indigenous to Northern Australia as well as India, and possesses good fattening properties.

*Microstena stipoides* (Oat Grass).—Where Kangaroo Grass grows this Grass is generally found, but does not suffer so much from overstocking as the former. It is a good fattening Grass, and vegetates freely during the winter.

*Anthistiria australis*.—This Grass is found in all parts of Australia, and is one of the most useful of the indigenous Grasses. Its nutritive qualities are at the highest when it begins to turn brown in autumn; and at this stage it is one of the best Grasses for sustaining the working powers of horses and cattle. When closely grazed by sheep it soon dies out.

*Panicum italicum*, L.—This Grass, notwithstanding its specific name, is of Indian origin, and is also a native of Northern Australia. It is a good pasture Grass, and possesses fattening properties and thrives well upon poor dry soils. Although an annual, it increases quickly, from being an abundant seed-bearer. The seeds, when pounded, mixed with water and baked, are used as food by the natives.

*Danthonia pectinata*, Lindl., and *Danthonia lappacea*, Lindl., the celebrated Mitchell Grasses, seeds of which were received through the courtesy of W. H. Barton, Esq., Aramac, are worthy of special mention. They are perennial desert Grasses, resisting drought, and are sought with avidity by stock. From their well-known fattening and drought-resisting properties they are so important as to be deserving of culture in their native habitats, and are likely to prove serviceable when introduced in many localities in which at present they are strangers.

### OUR BORDER FLOWERS—MULLEINS.

VERBASCUMS are not frequently met with in cultivation. Whether they are considered too common for dressed borders or are not sufficiently known, or, what is worse, are not cared for, I am not prepared to say, yet many of them are very ornamental. They may be despised and rejected, yet they are in possession of attractions that ought to secure for them more prominent places than they are at present occupying. No great amount of skill is required in their cultivation, for any good sandy loam will afford them a good medium to develop themselves in. They should not be crowded, and efficient drainage should be provided for them.

Our own Black Mullein, *Verbascum nigrum*, with its varieties are fine plants, and do us good service in the shrubbery and herbaceous border. From the Caucasus we have *Verbascum cupreum*, a rather tall-growing kind; but its copper-coloured flowers are very attractive. It flowers in early summer, and continues for a length of time. From that memorable mountain—of more than human interest—Mount Sinai, we have *Verbascum æthiopicum*, but it is rarely found in cultivation. *Verbascum fasciculatum* is similarly scarce. There are many other kinds, such as *Verbascum montanum*, *V. creticum*, *V. Thapsoides*, and *V. Lychnitis*, that deserve notice. *Verbascum phoeniceum* is one of the most attractive of the family. This, with its varieties, in a group are very beautiful, their colours being white, purple, and red.

Verbascums are increased by seed sown as soon as ripe, and by division of the roots in spring. When once established they last many years.—VERITAS.

### SOME SPECIES OF PRIMULA.—No. 1.

No more appropriate name could be applied to the genus, for nearly all the species are "the little firsts" of the year to flower. Our earliest authority, "The Greater Herball," published in 1561, says of the Primrose, "It is called Prymerolle or Primula of prime tyme, because it beareth the first floure in pryme tyme," that is in the spring; and Milton, as usual, was a true annalist when he wrote—

"The flowery May, who from her green lap throws  
The yellow Cowslip and the pale Primrose."

In that month they are in their greatest strength, but their advanced guard appears in April.

Lyte, who wrote a little after "The Greater Herball" was published, says, "The petie Mulleyns are called Cowslippes, Primeroses, and Oxelips. These herbes do floure in April, and sometimes also in March and February." They were two centuries ago special objects of culture; thus Gilbert in his "Florists' Vade-Mecum," published in 1683, says, "Many sorts were raised lately from seeds and given me by that industrious rare florist, my truly worthy friend Peter Egerton, Esq., of Boughton near Chester." Parkinson some years previously described twenty-one kinds. I have no doubt that Primrose is a corruption of the earliest name of the flower, for it has no resemblance to a Rose; but Primrolle is strictly applicable, being a compound of Anglo-Saxon words equivalent to "Spring-unfolding."

We will commence our notes with *PRIMULA LONGIFOLIA*, a native of the Levant, and introduced as long since as 1790.

Fig. 67.—*Primula longifolia*.

Its leaves are spatulate, toothed, smooth on both surfaces, elongating after the plant has flowered, and are rather erect.

The umbel is very erect, and bears many flowers of a pink colour.

This attractive species is of easy cultivation, and is adapted for the decoration of the spring garden, rockwork, and the conservatory. It is hardy, but is injured by excessive wet; a partially shaded place in summer is also desirable. The plants will flourish in ordinary garden soil, and are increased by division after flowering. For cultivation in pots they need to be potted in a mixture of fresh loam, leaf soil, and silver sand. A shaded place in the open air is suitable for the plants during the summer, a cold frame for preserving them during the winter, and the shelf of a greenhouse during the flowering period in the spring. The foliage is liable to the attacks of red spider, but healthy growth and occasional syringings, with a cool pure atmosphere, will preserve the plants from serious injury. The flowers, besides being pretty by their compact form and pleasing colour, emit a delicate and agreeable perfume.

#### MANURING AND PLANTING ROSES.

I HAVE been asked many times, What is the best manure for Roses? I think your correspondent "D., Deal," is right in recommending pig manure; but I like pig manure which comes from the stable first and was then thrown into the pigstye. The pigs cool the horse manure, and when thoroughly decayed it has the combined strength from the pig and also the ammonia from the horse, which renders it capital for the Rose, and far superior to any I know for the Rose either on the Briar or the Manetti both in light and heavy soils.

I like a good heavy dressing put on early in June, which will keep out the drought of summer, and then forked-in about the end of October, and another good dressing in November to keep out the frost. I think these seasons are the best for manuring. I also use this manure when planting, trenching the ground 2 feet deep, and mixing with it some chopped turf, which is also valuable.

My opinion is that Rose-growers would do better with their old Roses by taking them up once in five or six years and removing from the roots all the suckers and old, long, or decayed roots, and replanting in soil well trenched and manured. I may also add that this is the best time for that operation. I have treated my Roses in this way and it answers well.—C. H. KITCHING, *Woodstock*.

#### HYDE PARK.

It is probable that this name is a corruption of the Anglo-Saxon designation of part of the manor *Eia*, and which may have derived its title from *Ea*, running water, as the rivulet Tyburn passed through its entire length. The manor of Hyde, Mr. Walford says, was in the possession of the Abbey of Westminster at the time the Domesday Book was compounded, and remained in the hands of the monks until seized upon by King Henry at the time of the Reformation. Of the manor of Hyde we know that its woods afforded to the monks both firewood and shelter for their game and waterfowl; and there is extant a document in which William Boston the Abbot, and the rest of the Convent of Westminster, with their entire assent, consent, and agreement, handed over to His Majesty "the seyte, soyle, circuyte, and precincte of the manor of Hyde, with all the demayne lands, tenements, rentes, meadowes, and pastures of the said manor, with all other profytes and commodities to the same appertayning and belonging, which be now in the tenure and occupation of one John Arnold."

"Henry's main object in appropriating this estate," observes Mr. Larwood, "seems to have been to extend his hunting grounds to the north and west of London. As we have already seen, the king had previously purchased that plot of ground which afterwards became St. James's Park. Marylebone Park (now the Regent's Park and surrounding districts) formed already part of the royal domain; and thus the manor of Hyde, connected with these, gave him an uninterrupted hunting ground, which extended from his palace of Westminster to Hampstead Heath. That some such idea existed in the royal mind appears from a proclamation for the preservation of his game, issued in July, 1536, in which it is stated that 'As the King's most royal Majesty is desirous to have the games of hare, partridge, pheasant, and heron preserved in and about the honour of his palace of Westminster, for his own disport and pastime, no person, on the pain of imprisonment of their

bodies, and further punishment at His Majesty's will and pleasure, is to presume to hunt or hawk, from the palace of Westminster to St. Giles-in-the-Fields, and from thence to Islington, to Our Lady of the Oak, to Highgate, to Hornsey Park, and to Hampstead Heath.' It was, probably, also about this period that the manor of Hyde was made into a park—that is, enclosed with a fence or paling, and thus became still better adapted for the rearing and preserving of game. And here it may be fit to observe that its extent at that time and for long after was much greater than it is at present, reaching as far as Park Lane to the east and almost up to the site of Kensington Palace to the west."

Cunningham observes that to the passionate fondness of the early English sovereigns for the chase we owe in all probability the parks of London. What was a passion in our Williams and Edwards became in their successors a fashion also. Even the awkward and timid James deemed it a part of his king-

craft to affect a love of the chase. Hence the formation of St. James's Park by Henry VIII., and the retention of Hyde Park and Marybourne Park by that king and his successors, when other lands appropriated by the Crown at the dissolution of the monasteries were squandered away as lavishly as they were covetously grasped in the first instance. There are circumstances which would lead us to attribute to Henry VIII. a more extensive project than that of merely studding the country in the vicinity of the royal residence with deer parks.

Hyde Park occupies nearly 400 acres. The sheet of water ironically called the Serpentine, being nearly straight, was formed in 1770-3 according to the order of Queen Caroline; but the waterfall at its eastern end was not constructed until 1817. The angle which Apsley House occupies and a large portion of Kensington Gardens have been subtracted from the park.

Hyde Park was a favourite place of resort for those who

Fig. 68.—HYDE PARK—THE DELL.

brought in the 1st of May with the reverence once paid to it. Pepys breathes a sigh in his 'Diary' on the evening of the 30th April, 1661 (he was then on a pleasure jaunt), to this effect:—"I am sorry I am not in London to be at Hyde Park to-morrow morning, among the great gallants and ladies, which will be very fine." It was very fine, for Evelyn has entered in his 'Diary,' under the date of the identical 1st of May referred to by Pepys:—"I went to Hyde Park to take the air, where was His Majesty and an innumerable appearance of gallants and rich coaches, being now at time of universal festivity and joy." But even during the sway of the Puritans the Londoners assembled here "to do observance to May," as we learn from "Several Proceedings of State Affairs, 27th April to 4th May, 1654."—"Monday, 1st May. This day was more observed by people going a-maying than for divers years past, and indeed much sin committed by wicked meetings with fiddlers, drunkenness, ribaldry, and the like; great resort came to Hyde Park, many hundreds of coaches and gallants in attire, but most shameful powdered-hair men, and painted and spotted women. Some men played with a silver ball, and some took other recreation. But His Highness the Lord Protector went not thither nor any of the Lords of the Commonwealth, but were busy about the great affairs of the Commonwealth."

A resident has observed in a local periodical that a map

of Hyde Park about the year 1736 or 1737 shows the turnpike and gallows at Tyburn, and a double row of Walnut trees, with a wide gravel walk between, running from north to south parallel to the Park Lane. In the centre of this avenue is a circular reservoir belonging to the Chelsea Waterworks, and from which not only Kensington Palace and the suburb were supplied, but also "the new buildings about Oliver's Mount" (now Mount Street) "and the northern parts of Westminster." Mr. Larwood tells us that the machinery used for forcing the supply was at that time so primitive that the water had to be conveyed to the houses on the high ground near Grosvenor Square by means of a mill turned by horses.

This avenue of Walnut trees was standing till about the year 1810, when most of the trees, being much decayed and in danger of being blown down whenever the wind was high, were cut down, their wood being designed to make stocks for the muskets of our infantry.

In the map the "Ring" is marked with a large circle, apparently about 150 yards to the north of the east end of the Serpentine. Round the "Ring" stands a square of large trees, a few of which may, perhaps, still be standing. There is a small brook which runs into the Serpentine near the present boathouse from the neighbourhood of the Uxbridge Road, and two small ponds of water are marked towards the south-east corner—one nearly where the statue of Achilles

now stands, and the other nearer to the rear of Apsley House. The map shows also the two roads running parallel to the Serpentine on the south, marked respectively as "The King's Old Road or Lamp Road," and "The King's New Road," the former corresponding nearly with the Rotten Row of our time, and the latter running, as now, inside the park close to the Knightsbridge Road and Kensington Gore. On the north of the Serpentine there is apparently no regular road, except for about 100 yards from the eastern end, where it bends to the north away from the water towards the "Ring."

The "Ring" was a place of fashionable resort down to the reign of George II., when it was partly destroyed in the formation of the Serpentine river. Remnants of it were still traceable at the beginning of the century on the high ground directly behind the farmhouse. A few very old trees are even now to be found on that spot. Some of these are indeed ancient enough to have formed part of the identical trees round which the wits and beauties drove in their carriages, and, as Pennant says, "in their rotation exchanged, as they passed, smiles and nods, compliments or smart repartees." Plain as it was, it must have been a pleasant spot on a summer's afternoon. Situated on an upland space of ground one may imagine the pleasurable prospect from hence when all around was open country, and nothing intercepted the view from the Surrey hills to the high grounds of Hampstead and Highgate. One can easily imagine how delightful it must have been for the ladies who "came in their carriages from the hot play-house and close confined streets of the city, to be fanned by soft winds which blew over broad acres of ripening corn, flowering Clover, and newly mown hay, or rustled through the Reeds and Willows on the banks of the pools."

Walker, in "The Original," in 1835, speaks of the "Ring" as being still traceable round a clump of trees near to the foot barracks, and enclosing an area of about 90 yards in diameter and 45 yards wide. "Here," he adds, "used to assemble all the fashions of the day, now diffused round the whole park, besides what is taken off by the Regent's Park."

Yet there still is no outdoor spot in London that has such a world-wide reputation as this, and for a stranger to be in London during the season and not to visit it would be to miss a sight where beauty, fashion, wealth, and luxury, and not a few men of rank and distinction from all parts of Europe, congregate. To the lovers of horses, too, the sight is unequalled, for here in the season he will see some of the finest animals that money and knowledge of quality can procure, also every kind of fashionable vehicle which the ingenuity of carriage builders can produce. There is a beautiful shady walk on each side of the Ladies' Mile, and those walks will improve every year, for the trees are still young, but the foliage is very fine and indicates health. Under those lofty trees a few years ago there was nothing but weeds and dust, and everything that made a place look unsightly; but now everything is done that can be done to make it look beautiful. The Albert Gate end of the Serpentine, which was formerly nothing but a dirty ditch, is now a charming little dell and an object of much admiration. The floral department of Hyde Park is under the superintendence of Mr. Gibson, and each summer's display gives evidence of his taste and skill.

## WILL POTATOES RUN OUT?

By Professor W. J. BEAL, Michigan Agricultural College.

AGAIN, as usual we have raised many varieties of Potatoes—this year about 250. Two moderate-sized tubers of each kind were used as seed for six hills. They were planted on sod ground which had been seeded for several years. The ground was in good condition and had yielded two crops a-year of orchard Grass, Clover, and Lucern. The soil was a sandy loam, and ploughed in the autumn, cultivated and top-dressed with fine manure in the spring. In ordinary seasons the crop would have been a good one, but this year it was very light. The weather was very favourable till some time in June, when it suddenly changed from cool and cloudy to hot and plenty of sunlight. Potatoes almost stopped growing on account of the sudden change.

In former years the Potatoes in small quantity here noticed were planted on old garden soil—I mean on soil which had been in cultivation for some years in succession. They have been manured in a variety of ways, not very heavily, but generally with a good dressing of fine manure and ashes. The Potatoes have never been planted on the same piece of ground in two successive seasons, but they have been shifted about on

similar soil, on different parts of about five to eight acres. Two years ago the number of varieties was much increased. Previous to that time, for some six years, there had been fifty to eighty varieties in the garden. For some years the yield has been carefully noted, usually by weighing the tubers of each hill, or each set of hills. Of course we should expect a variation in the yield for different hills in the same year of the same sort, even if we treated them in all respects as near alike as possible.

The chief object of planting so many kinds in this manner is to watch the changes from year to year in yield, health, quality, &c. We all know for family use that we cannot measure the value of a crop of Potatoes by the scales or bushel basket, still the yield is of great importance. The ideal Potato must, at least, be productive of even-sized tubers close together in the hill, with few or no small ones. It must have full eyes and even surface, a light or red colour or spotted, must be of good quality for all seasons of the year; and now that the beetles have become so troublesome, the model Potato should ripen early in the season.

It would require needless space to give here the weight of each sort. This season the greatest yield for six hills was 19 lbs. 7 ozs.; last year 21 lbs. 1 oz. for three hills. On no two years has the same variety headed the list in productiveness. This year it was Long Pond; last year, Early White; the year before it was Climax. In comparing the yield for the past two seasons I find all those yielding well this year yielded well last year, and that those yielding lightest last year hold somewhere near the same rank this year.

In the report for 1868, before I came to the College, the comparative yield is given of fifty-five varieties of Potatoes. With few exceptions the tubers of these have been used on the garden ever since. They have all decreased in yield, notwithstanding the garden is now much more productive of most crops than it was eight years ago. In 1868, Casco was reported as yielding at the rate of 340 bushels to the acre; last year three hills produced about half an ounce, although it was a remarkably good year for the yield of Potatoes in our locality.

This year it ran out entirely. We did not get one tuber, not even a small one. In 1868 Colebrook gave at the rate of 155 bushels to the acre; Davis Seedling, 276 bushels; Prince Albert, 262 bushels; Coppermine, 176 bushels. Last year they yielded respectively for three hills of each variety—Colebrook, 2 lbs. 9 ozs.; Davis Seedling, 5 lbs. 6 ozs.; Prince Albert, 1 lb. 11 ozs.; Coppermine, 4 lbs. 9 ozs. This year Colebrook yields for six hills (twice as many hills as reported last year) not one tuber, large or small; Davis Seedling, not one tuber; Prince Albert, one-fourth of an ounce, a few very small tubers; Coppermine,  $\frac{1}{2}$  oz. Other examples could be added of a similar nature.

The question as to whether varieties wear out has long been discussed. Mr. Knight, the famous English horticulturist, maintained that they did, and gave what he supposed were good illustrations to prove it. Others since his time, as well as his contemporaries, believed otherwise. I have seen Indian Corn which had been kept for ten or more years on the same farm. Although the farm was a good one and the land well managed, the ears of corn grew shorter, the kernels shorter and rounder at the ends. The corn mentioned was the White Dent, in the latitude of Lansing, Michigan. I should be glad to hear from others who have kept the seed continuously on the same farm for many years. It is a common notion that sheep do better when changed occasionally from one farm to another, or from one neighbourhood to another, even where they were under the care of a good master before changing.

It would be interesting to know whether any of these varieties of Potatoes which have been kept here for some years would revive if their seed were sent to distant portions of our country and well treated. To test this point, last spring I sent tubers from our garden to Kansas Agricultural College and another set to Ohio Agricultural College at Columbus. The Professors of agriculture in each of these two institutions agreed to treat them the same as we have treated them, and report the result for comparison. It may be said that the Potatoes in the cases noticed above ran out because they were not fairly treated, that they were not properly fertilised or cultivated, yet I do not think this the only cause. Of the newer sorts of Potatoes, as lately as Early Vermont, Compton's Surprise, Brownell's Beauty, &c., planted on similar ground with similar treatment, we have raised excellent crops nearly every year. In this connection I may mention a fact, though some will doubtless find other explanations than the degenerating of

varieties. In many parts of southern Michigan the Wheat crop is lighter than it used to be. The usual explanation given is that Wheat has been too often raised on the same ground. But in many instances which have been noticed by our most observing farmers, a newly-cleared piece of timbered land for its first crop does not produce nearly so well as in early times, say thirty years ago, when the country contained much land cleared every year.—(*Rural New Yorker*.)

### CARTER'S METROPOLITAN ROOT SHOW.

THE annual displays at the Agricultural Hall have always been worthy of note and inspection by those who are identified with the cultivation of roots, both of the farm and the garden. The display this year was of great magnitude, farm produce necessarily preponderating, and the quality of the roots was decidedly greater than on any past occasion. The rulings of competent judges have had an educational effect, and now size must be combined with cleanliness of growth and solidity to merit approval. Some idea of the extent of the Show may be formed when it is stated that it occupied the floor of a gallery about 250 yards in length and 20 in width; and the collections were not only of high but of level excellence, which must have given the Judges no small amount of trouble in making their awards. For the prizes, including a ten-guinea silver cup for Carter's Hardy Prize-winner Swede, forty collections were spread, Carter's Warden Mangold sixty-eight, Carter's Red Mammoth Mangold fifty-two, Intermediate twenty-four, and similar numbers of exhibits in many other classes. The weights of the Mangolds varied from 40 to 60 lbs., and many Swedes approached 20 lbs. weight. It was not mere size, however, so much as high quality and distinctness of the several varieties which were the prevailing characteristics of the Show. About a hundred dishes of Potatoes were exhibited, and prizes were awarded for Snowflake, Breadfruit, Excelsior, and Prince of Wales. The best collection—eighteen varieties—came from Mr. Lumsden, Bloxholm; the largest Snowflakes from Mr. Penny, Sandringham. Onions were highly superior, indeed finer bulbs were never staged at any show. The White Spanish type predominated; the Pinesfield variety being well in advance of its congeners. The Show throughout was a credit to Messrs. Carter and their numerous customers who competed.

### NOTES ON VILLA AND SUBURBAN GARDENING.

**GROWING MUSHROOMS.**—In this part of the country the latter part of the summer has been rather more favourable than common for the natural growth of Mushrooms. They have been collected by cartloads, and have met with a ready sale in the markets; yet, notwithstanding that, the artificial culture of this esteemed esculent must not be neglected by those desiring a supply throughout the winter. I will enumerate, therefore, a few principal points to be attended to in their culture. Firstly, do not delay any longer in preparing the materials for the beds. These consist of horse droppings, to be collected as fresh as possible, with a very little very short straw left and mixed with them, and put in a heap to sweat, and be sheltered from wet in some outhouse. If the heap should be small and showing no signs of heating, throw two or three mats over it, and this will help to induce fermentation. When such is the case turn the heap inside out and mix the whole well together. It is important to understand that this heap is not to lie till it has exhausted itself by heating, but as soon as the fermentation has partially subsided and the material is in a moderate state as to dryness it may be put into the bed, but if too wet mix a few fresh oak leaves with the dung; but in towns where these cannot be obtained a little of the litter that was shaken from the dung may be chopped up and added by mixing.

In making the bed take care that the material is put in in thin layers all over the bed, so that the heating may be regular, for if put by barrowfuls without an attempt to spread it out evenly, the heating becomes violent at one place and the bed is cool in another. Tread or press every layer down as firmly as possible, for if the dung is in good order it will have a kind of spring in it that will prevent it being made too firm, but if too wet it cakes and is not in good condition. I am an advocate for having the beds rather deeper than is usual in Mushroom houses—about 18 inches at the front and quite 2 feet at the back where the bed usually rests against a cold wall, otherwise I see no reason for having a bed elevated at the back. After being trodden down sticks should be inserted in it at two or more places to tell when the heat rises. If it is long in coming up cover the bed with a layer of straw, which will help it much. When the heat does rise and increases in intensity day by day no spawning must be done, but when the heat commences declining and is reduced to a little more than new-milk warmth about 3 or 4 inches under the surface, spawning may be done with safety by making holes to that depth and inserting small pieces of the size of a duck's egg, and pressing them in

tightly, filling the holes up, and making all level on the surface and closing the house. The bed should now be watched carefully, and when the heat is going down too rapidly cover again with straw, and this will prevent the temperature falling too low. In about a fortnight, if all goes on well, the spawn will begin to run—that is, will throw out white hair-like threads into the dung, and by trying two or three different parts of the bed, and finding it generally so, the surface may be soiled over.

The soil should be sifted fine and not be too close in texture, or the surface of it when beaten down becomes caked, and the Mushrooms cannot come through, therefore let it be just sufficient to cling together. Cover the bed with 2 inches of soil, so that when beaten down there is a good inch in thickness. The surface should then be covered over with straw. The heat of the house or shed should be kept up to 55° or 60° at first, either by hot water or by a heap of heating dung. When the small Mushrooms appear the bed may be watered if it appears dry, but not without, and the crop will soon be ready for gathering. After the first crop is gathered the bed may be watered if needed and covered over again for the next crop, and so on till the bed is exhausted.

It matters not where Mushrooms are grown, the same principles of culture must be pursued. Some grow them in boxes, tubs, or even large pots, and if the conditions of making up the material and affording the necessary warmth for starting the spawn—a point never to be neglected—and the atmosphere is kept even in temperature, no one need be afraid of attempting the culture of Mushrooms, nor doubt of being successful.—THOMAS RECORD.

### DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

#### HARDY FRUIT GARDEN.

APPLES and Pears in the fruit room are not keeping well this year. Much of the fruit has been injured by the Apple-boring maggot. Some seasons we have been almost exempt from this pest, and have fancied that it would not trouble us much more, but it has again attacked the fruit to a large extent. We still fancy the best way to keep the maggot in check is to gather all the fruit attacked by it, and destroy it, thus preventing the further increase of the pest. We frequently look over the fruit in the fruit room and remove such as show symptoms of decay, to prevent the injury from extending further. This is work that ought by no means to be neglected.

In a previous number instructions were given to have ground prepared for the planting of fruit trees. No time ought to be lost now in placing the trees in their stations. Nearly all the principal nurserymen have a great demand for all sorts of trained trees, and the best specimens are bought up early in the season. It is not an uncommon occurrence for amateurs, and even gardeners of experience, to place rich compost round the roots of the trees, and we have even seen manure used without the addition of any soil to it. Now, as a general rule, garden soil is rich in manurial properties, and is not in the best condition to be applied to the roots of the trees, and when turfy loam can be obtained there is nothing better for planting in; a larger proportion of healthy fibrous roots are made in this than in anything else, and should it be necessary to remove the trees next season it can be done without any injury to them. See that the holes for the roots are large enough to allow them to be spread out to their fullest extent, place 2 or 3 inches of the loam in the bottom of the hole, and then place the roots of the tree in, filling up with loam, carefully working it in amongst the roots, and when the operation is finished the tree ought not to be deeper in the ground than it was before its removal. Pears on the Quince stock should be planted to the union of the stock with the scion. All newly-planted trees should have a stout stick placed to them to prevent their swaying with the wind. Wall trees require to be planted in a similar manner. The bole of the tree should be 2 or 3 inches from the wall, and the tree ought not to be fastened to the wall until the ground settles down, which it will do sufficiently in the course of two months. All small fruits, such as Raspberry, Currant, and Gooseberry bushes, should be planted at once. All of them, and Raspberries especially, require rich soil. The ground ought to be trenched and well manured. We merely plant in the ordinary soil, and for all newly-planted trees and bushes some decayed manure is placed on the surface of the ground over the roots. Nothing is better for this purpose than spent frame dung or the clearing-out of old Mushroom beds.

We have commenced pruning Gooseberry and Currant bushes. We thin the wood out well, spurring the young wood close back to the old. What young wood is allowed to remain on Gooseberries is shortened back but little. Red and White Currants have it cut back more closely. Black Currant bushes require no pruning, except to thin-out the branches when they become crowded. After pruning the bushes clear the prunings off, as they are unsightly when left on the ground; then give a good dressing of manure, and fork the ground over neatly, burying

the manure under the surface. Should the Gooseberry bushes have been infested with the caterpillar the previous season remove the surface soil from under them to the depth of 4 inches, as this portion contains the larvæ of the caterpillars, which may be destroyed by being turned 9 inches or a foot below the surface.

Box-edging that requires relaying ought to be done now; we have found the edgings do better when planted at this season than at any other. Edgings formed of tiles or stonework if out of order should also be attended to.

#### PINE HOUSES.

We have had some good fruit from plants put out in a bed in rich turfy loam. They had a depth of soil of about 15 inches, and were 18 inches apart, the sorts being Smooth-leaved Cayenne and Charlotte Rothschild. Our experience with the above two sorts has been a very extended one, and whether as pot plants or for planting out in the beds the Cayennes are the best. The foreign growers seem to take to this sort more than any other, and they seem to be very successful with it. Specimens have been sent into Covent Garden very recently weighing 12 lbs. each. It is singular that the fruit should not be of good quality, at least in comparison with the same sort grown in England, as the crown and appearance of the fruit cannot be distinguished from home-grown fruit. We have given the temperatures of the different divisions of the houses in previous numbers, and these temperatures must still be maintained. Plants in the fruiting house, on which there are fruit in different stages of development, must have water supplied to them when it is required, but that is not very often at this season. Plants at rest intended to be started early next year ought not to have any water at the roots, and the atmosphere should be comparatively dry. Some Pine-growers keep their plants in growth all through the winter months, but it is better to let them rest at that season. They may be started into growth with the lengthening days of the new year.

**Figs in Pots.**—No fruit trees do better in pots than the Fig. The restriction to which the roots are subjected in the confined space of a pot seems just what the tree requires to make it produce short-jointed fruitful wood. When this object has been gained it is easy to swell the fruit up to a large size and have it of the best quality by rich surface dressings, and a little manure water occasionally will be of advantage. When the dressing has been applied to the surface of the pots it is interesting to watch the rapid manner in which the thick fleshy roots push into it, and how quickly the effect is seen in the more healthy dark green hue which the leaves assume. Those who intend to force a few Figs in pots early should now make the necessary arrangements. A gentle bottom heat promotes root-action, and is an advantage to the trees early in the year. Beds of oak or beech leaves produce a mild lasting heat, and throw off sufficient moisture to produce an atmosphere well adapted to the health of the trees. The pots may be plunged two-thirds of their depth in such a bed as this. No syringing will be required except a gentle dewing overhead in warm days. The trees may be started with a night temperature of 45°, gradually increasing to 55°, and this should not be exceeded until the leaves have grown nearly their full size. The pots must not be under-watered, but on the other hand the Fig detests stagnant soil.

#### GREENHOUSE AND CONSERVATORY.

With a large stock of the best sorts of Chrysanthemums these structures are as gay now as it is possible to have them at any season of the year. What a boon it is to have such fine flowers at this season, either for cut flowers or other decorative purposes. The flowers during damp weather suffer much from mould, the petals damp, and decay rapidly spreads. The leaves also suffer much from mildew, which, however, is easily destroyed if taken in time, by dusting with dry sulphur. When the leaves of any plant are much infested with mildew dry sulphur does not always destroy it on the first or even second application. A good plan in such a case is to lay the plant on its side and syringe it regularly over the leaves with soapy water in which has been mixed a handful of flowers of sulphur to the gallon. The object of laying the plant on its side is to prevent the water from draining to the roots, as it injures them.

All plants must be kept perfectly free from insect pests. Red spider attacks hardwooded specimens in a most insidious manner, and sometimes much damage is done to the plants before the pest is discovered. Camellias do not often fall a prey to this parasite, but it does sometimes attack the under sides of the leaves, causing them to become rusty. When the stock of plants is not large and time permits, the best plan is to wash the leaves and stems, including all the branches, with soapy water. This will cleanse them from scale as well as from all other insects and accumulations of dirt.

Some of the earliest Cinerarias are showing flower, and those that will be at their best in March and April are growing very strongly in a cool pit. The Cineraria does not endure much sun, and the less artificial heat that is applied to the plants the better. In fine weather the lights and front ventilators are open to their fullest extent to prevent damp from injuring the

leaves. The side growths we tie down either by placing short sticks in the pots or a wire round the rim to which the shoots are tied, not too much at once, but gradually until the outer flower stems are brought down to very nearly a horizontal position; the plants when in flower will form half a ball.

Stage and fancy Pelargoniums intended to form handsome specimens require a little training at present. The weather having been so warm the plants are making considerable growth, and those not bushy enough have been stopped. Pelargoniums and Cinerarias are very much subject to green fly, the latter also suffers from the attacks of thrips. They must be destroyed by fumigation, and this must be continued until not even a solitary specimen is left alive. Calceolarias require very similar treatment to Cinerarias, and suffer equally from the attacks of green fly. Decay and mildew spreads rapidly at this season, and all of it should be removed as soon as it is perceived.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Ewing & Co., Royal Norfolk Nurseries, Eaton, Norwich.—*Catalogue of Fruit, Forest, and Ornamental Trees, Coniferae, Evergreens, &c.*

Richard Dean, Ranelagh Road, Ealing, London, W., and Seed Grounds, Bedford, Hounslow, W.—*Catalogue of New and Choice Primroses, Polyanthus, Daisies, Hepaticas, Bedding Pansies and Violas, Hardy Herbaceous and other Plants, also of Choice Potatoes.*

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

LEEDS. November 24th and 25th. Mr. George Hemming, Hon. Sec.  
ISLE OF THANET. August 30th, 1877. Mr. C. D. Smith, Hon. Sec.

#### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

**GATHERING LEAVES (H.).**—When leaves are very numerous we know of no better plan than raking them together with wooden rakes and putting them into carts with large, long-curved pronged forks. In clearing lawns we first use rakes, then flush with birch brooms, placing the leaves in large wheelbarrows with the assistance of two pieces of board—leaf boards.

**HEATING BY GAS (A Five-years Subscriber).**—Burning gas, unless the fumes from it are entirely conveyed into the air outside, is injurious to Vines and plants.

**"WILD FLOWERS" (W. D. L.).**—The publication will be continued until all our native flowers are portrayed, otherwise the work would be imperfect.

**THE MANETTI ROSE (R. W. S.).**—Mr. W. Paul says, "The Manetti Rose was raised from seed by Signor Manetti of the Botanic Garden, Monza. It was introduced by Mr. Rivers about the year 1837, who received it from Signor Crivelli of Como. I never heard from what species or variety it was raised, and I have never been able to refer it to any species that I have been acquainted with, and have always set it down as a garden hybrid or cross-bred."

**HOLLIES (Iris).**—We cannot name varieties that are multitudinous and nearly alike.

**ACACIA RICEANA (A Constant Reader).**—It is an evergreen.

**EXHIBITED FRUIT WRONGLY NAMED (Juvenile).**—Judges in disqualifying fruit at an exhibition, owing to the said fruit being wrongly named, need not name it properly.

**EXHIBITING CARNATIONS AND PICOTÉES.**—No more need be published.

**NOTICE TO LEAVE (Peter Parley).**—"A head gardener was engaged several years since by word of mouth, at so much salary a year, paid quarterly, no mention being made as to notice to quit. What notice should be given on either side?" It has been decided in a similar case that a month's notice must be given.

**THORN DECAYING (Surrey).**—The cause is difficult to determine. We have seen similar instances where the trees were growing in hot gravelly soil. The excessive heat and drought of the past summer caused the branches of many trees to shrivel prematurely.

**BUCKLAND SWEETWATER GRAPE (Reader).**—When well managed this is one of the best early White Grapes; but the fruit is watery and flavourless unless well exposed to the sun. It is well adapted for exhibition early in the year, and at that time, and when in good condition, brings as good a price in Covent Garden as Black Hamburgh. Inferior fruit that has not been exposed to the sun is of but little value.

**MICE EATING CROCUS BULBS (G. G.).**—The best plan is to trap the mice. Lay a flower pot down on its side, and place the trap in it to keep it dry.

**PRUNING VINES (Idem).**—Vines should be pruned as soon as the leaves

have fallen and the Grapes are gathered. *Bouvardias* may be pruned to prevent the plants from becoming leggy.

**VINES IN GREENHOUSE (J. W.).**—If you intend to grow plants underneath the Vines the rods must be more than 2 feet apart. We advise you to train up canes 4 feet apart from the horizontal main stem, and spur them back annually. You may renew the rods at regular intervals, say one each year. The two rods alluded to in your letter we advise you to cut back, leaving about 5 feet of the wood.

**SCALE ON APPLE AND PEAR TREES (J. R. Lisburn).**—We have destroyed this pest by painting the branches in winter with boiled oil, but a number of the blossom buds were destroyed by it. We have not tried paraffin to destroy scale, but no doubt it would do so, as it is sudden death to American blight. Until this year we had not tried it further than just to touch the affected part of the tree with a brush dipped in the paraffin. This season one of the Apple trees was by accident coated over entirely with paraffin, and we will state the result next season. We have seen the small Pear scale destroyed by syringing the trees with water heated to 145°.

**NAMES OF FRUITS (L. Garnett).**—1, Vicar of Winkfield; 2, Hollandbury; 3, Pearson's Plate; 4, Not known. (*Mr. Pye Smith*).—The two large Pears are Vicar of Winkfield, and the round one Millot de Nancy.

**NAMES OF PLANTS (Amateur).**—Henslow's "Botanical Dictionary" will suit you.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### CAN A POULTRY FARM PAY?

I do not feel competent to deny the conclusions at which the writer arrives, while I must take exception to his figures, and shall be glad if I can call forth the opinions and statistics of some really practical men on the subject, for as far as my own experience goes I can only think "G. R. H." is an enthusiast, and we know they are always able to prove their own conclusions, while ordinary mortals not unfrequently come to grief in trying to attain similar results.

I am very fond of reliable statistics, but in reading or studying them always bear in mind some advice given me years ago—"Friend, thy figures will never tell thee lies if thou puttest them down correctly," and the object of my writing this is to ask from practical men if "G. R. H." has fulfilled the latter condition.

I commenced keeping poultry some ten or twelve years since, and for the first twelve months kept an exact record of every egg obtained. I had six hens and seven pullets, which during the year produced 1114 eggs, or say roughly, ninety each. I thought they ought to have done much better, and so gave up recording what I could only regard as their faults or failings; and although I have kept poultry ever since, have had no reason to doubt this average is very far off the mark, and would therefore ask—Can "G. R. H." persuade his hens to lay 150 eggs each on an average? Can he make each of his 4000 eggs produce a chicken? Can he make fifty hens hatch and rear 4000 chickens? Can he rear 4000 chickens until fit for market without one casualty? Can he obtain 1*d.* each for his eggs on an average? Can he send his fowls and eggs to market for nothing? As it appears to me that if a man and woman are to attend to such a farm they would not have much time for such matter-of-fact duties as this.

I could lengthen my string of questions by such as whether "G. R. H." can obtain his stock and cultivate his land for nothing, but think I have suggested enough to place the balance on opposite side of account; and though fully prepared to admit it may be, and frequently is, kept on the right side, I cannot regard your correspondent's estimate as at all reliable, and shall read with great interest any remarks which men of experience may furnish, and will, in conclusion, only express a hope that "G. R. H." will accept my criticism in the spirit it is offered, which is simply a desire to arrive at hard facts.—*EDITH WESTON.*

### CRYSTAL PALACE SHOW.

The great "National" is not too ambitious a term to describe this superb Show—this Show of shows, for the best of English fanciers are present. Scotch fanciers, in spite of cold (aye, very cold travelling) weather this year, come south to it; and Irish fanciers face the rough channel and meet their English brethren in the Palace. 'Tis getting an old Show now. I don't care to remember how many years we have met together to look at the "doos." I see alterations in fanciers' faces and figures. There's Mr. So-and-so, how grey he has grown! Then, dear me! what a full waistcoat the once Adonis-like Mr. — has! And there's another coming to "the lean and slippered pantaloon." However, whoever is altered there's the father of the fancy, Mr. Esquilant, not a bit changed, as lively as ever and as young as ever. I wish I had his recipe for retaining young looks. Then there is the Show, same place, same pens. While other shows once annual have departed, some promised and not fulfilled their promises, the Palace Show like Christmas comes surely once a-year. It may take for its motto

"Shows may come, and shows may go,  
But I go on for ever."

Some names I miss from the catalogue, names of fanciers of

high repute and possessing many birds. I sincerely, and with the best feeling towards the fancy and towards all fanciers, venture to hope their names will be in the catalogue next year. There is one observable difference in the Show in general this year—no Rabbits are there. Well, perhaps it is best to keep to feather, and not have fur and feather together. But here are the Pouters standing up and looking me in the face and claiming my attention. What a triumph it was to make a down-looking horizontal-placed little bird stand up straight like a man; a bird prone turned into a bird tall, and looking not prone but upwards. Before speaking of the Pouter classes I must put on record what was not, I believe, in the schedule, and I do not see it mentioned in the catalogue—viz., that a challenge cup value fifteen guineas was presented by Captain Norman Hill for the best standard Pied Pouter cock to be competed for this year at the Crystal Palace, at Belfast, and at Edinburgh Shows. This prize to be for the best standard Pied cock exhibited, and to be competed for until the same bird receives the highest award on three different (not necessarily consecutive) occasions. This prize would establish the fact of a certain bird being the best Pouter in the United Kingdom of his day—a bird, I need not say, that would be looked at with the highest possible interest. Mr. McCulloch's Blue Pied cock, No. 2606, was the winner (one turn) of this cup this year in England.

**POUTERS, Blue Pied Cocks.**—The above-named bird first, a very grand bird; the defects being in his fine colour, a few ticks, and his bars not being wholly clear. Second, Mr. Fulton's fine bird, but the legs a little too forward, hence the body thrown a little out of balance. Third, Rev. W. J. Burdett's; a very superior bird with good bars, but his legs standing wide. This class had thirteen entries. **Black Pied.**—First Fulton (2612), a fine large bird with good crop, but droops his wings a little. Second Pratt (2613), a pleasing slender bird, but his crop smaller. Third, Messrs. Ridley & Dye, deserving its place; and a very highly commended, same owners, equally deserving its notice. **Red or Yellow Cocks.**—First a good limbed and cropped bird of Mr. Fulton's. Second, McCulloch, a good-coloured Yellow, and well marked but short flights. Third, another good Yellow, Ridley and Dye. There were three good Yellows near each other. 2624 (highly commended), the third and the second prizes. A very highly commended (Gill), a large-limbed and good-coloured bird. **White Cocks.**—First, no question about his place, Mr. Stiles's, and his bird in every way "stilis," slender, fine-cropped, excellent. Second, Fulton, a long but rather heavy bird. Third, Ridley & Dye, good, but smaller size. **Any colour Cocks bred in 1876.**—First-and-cup, Ridley & Dye, a Blue and very promising; may he fulfil his promises; the bars extremely good. Second a Blue, McCulloch. Third a Yellow, Blacklock, somewhat wanting in limb.

**POUTER HENS.**—I always am pleased when I get to them, they show so well. Like all ladies they like attention, and, like most, readily respond to it: all this very feminine. **Blue Pied Hens.**—First, Fulton, a grand hen, but a little bishoped. Second another of same owner, but somewhat hog-backed, at least so she seemed. Third, Ridley & Dye, a very superior bird. This a good class. **Black Pied Hens.**—First-and-cup, Pratt, the best hen in the Show. Second, same owner, a rather heavy cock-like bird. Third, Ridley & Dye. **Yellow and Red Hens.**—The Yellows are evidently looking up and appear in stronger numbers. First a Red, good colour and marking (Fulton). Second a Yellow (Pratt), pale, but a good hen. Third another Yellow (Ridley & Dye). **White Hens.**—Mrs. Ladd's superb hen first; this bird any fancier may well be proud of. Second Fulton. Third Ridley & Dye. Next we come to the young hens of any colour. First, McCulloch, a Blue hen; a very long bird, but wide in the legs. Second, Fulton, a better-limbed Blue. Third, Fulton, a Red of a very good dark colour. Very highly commended, a very good Blue, and deserving a prize; pity she has not better bars.

Such were the Pouters: 140 pens in all. The classes well filled, and the whole admirably judged by Mr. M. Stuart.

**The Pigmy Pouter Cocks**, fourteen in number, formed a good class. First-and-cup, Fulton, cream with white bars; the best by far. Second a White, and a very good bird. Third, Mr. C. B. Child, deserving its place. Mr. Tegetmeier and Mr. Holloway also showed some very good birds in this class, which as a class must be pronounced excellent. Pigmy hens quite matched the cocks. First a White of Mr. Holloway's; second a better-limbed bird than first; third Mr. Child.

**CARRIERS.**—**Black Cocks.**—First-and-cup, Mr. Maynard; wattle very large, fine frame, but a little thick in throat. Second, Fulton, a very stylish bird, with better neck than first. Third Mr. Hedley. Class a good one. **Black Hens.**—First-and-cup Mr. Maynard; second, Beckwith; third, Heritage. This class quite equal as a whole to the cocks. **Dun Cocks.**—First, Mr. Hedley, a bird possessing colour, size, and style. Next to it and coming second, Ridley & Dye's, a bird with a marvellously beautiful walnut wattle; the best in the Show as to this point but bad in colour. These two birds were well judged, but the placing them must have cost some thought. **Dun Hens.**—First

Maynard, good of its age; second, Nicholls, a bird of style; third Hedley. A great many highly commended in this class. *Any other Colour*.—Why not call this a class for Blues? for all were Blues save one, and Blue Carriers deserve that they should be alone and recognised. First, Massey, a thorough good Blue; second, Fulton, Blue again; third, Beckwith, Blue too. The Blues were fine in frame, but colour somewhat dingy or smoky, and a few beaks too Dragon-like—not straight enough. The one White was 2815 (Crisp), and very pretty. The Blue hens inferior.

Next came the young Carriers of this year, and it may at once be said that these were not an advance on last year, though some few were remarkable birds. Among these few I would notice the first-and-cup Black cock (Griffiths), a grand style of bird and by far the best of its age in the Show; good limb, good length of feather, and if he goes on all right will be a superb bird. Then I may note the first-and-cup Dun hen (Fulton), a bird with a beautifully straight beak; also first-and-cup Blue cock, fine length and fine head, but beak a little too down. *Any Colour, Cock or Hen*.—Mr. Ord's Pied bird, an old friend, a good bird to breed Whites from; also a Pied pair, very observable and deserving, and I should like to see more Pies.

Following the Carriers came their cousins the DRAGOONS, some of them scarcely cousins "once removed." The entry was a large one—185 pens in all. No one can complain of the fancy becoming tired of the old varieties. Mr. R. Woods was as usual very successful; but the second Blue cock (Mr. Tegetmeier) was a bird of most exquisite colour. The *Silver* cocks with black bars were not numerous, but extremely good, the bar becoming blacker and clearer. The *Red and Yellow* cocks.—First-and-cup Yellow; third a very good-coloured Red, same owner (Woods). The Blue hens were dainty and choice; the *Brown-barred Silver* hens, that good old sort, were up to the mark, and from his perseverance and success might be called "Bishop's own." The *Yellow* hens. First prize a beautiful-coloured bird; third a very rich colour. Next came the *Grizzles*, a very ancient variety recently revived. Once at the Crystal Palace Show only one appeared, now a class. With these might be classed the *Chequers*, instead of putting them with the Whites, which are best seen alone. The result was two *Chequers*, an altogether inferior colour taking two out of the three prizes among the hens of 1876. The young birds were very good well-grown Dragoons in all their classes.

ALMOND TUMBLERS, Cocks, any age.—First-and-cup 3152 (Hallam), beautifully spangled on shoulders and breast, and having good carriage; second same owner, rather dark hackle. A good class. *Almond* hens.—First 3168 (Fulton), good rich colour, a little wanting in style; second 3171 (Yardley), one flight too light, barring this better than first. Next I came upon a remarkably good class, the *Almonds* of 1876.—First-and-cup 3184 (Hallam), an excellent ground colour. The *Mottled Shortfaces* were seven in number. Would that these exquisite little birds were ten times as numerous. First, second, and third to one breeder, Mr. Henning, greatly to his credit. Tumblers, *Bald or Beard*, fourteen birds; more than usual. First 3201 (Woodhouse), a good Blue Bald; near it 3200, a good Red, very good in colour (Murphy), but not noticed; third (Fulton) a Blue Bald. This hard-to-breed class very praiseworthy. In the *Any other variety Shortfaces* the *Agates* proved very numerous, Mr. Beckwith's first-and-cup cock highly to be praised. The first hen a Kite, but as a rule the *Agates* won; the third hen (Hallam) a very good-marked bird.

BARBS, cocks.—First Mr. Hedley, a marvellous skill and short face. There was a wondrously good Yellow hen first-and-cup (Bryce). The young Barbs may be called double x. Some of their eyes were beautifully clear, as Nos. 3662 (Hedley), and 3291 (Firth). 3290 (Hedley) a capital Red.

Following the Barbs came the *Jacobins*, numbering 136 pens, the largest and grandest class ever shown. The *Yellows* particularly improved in colour, the rich tint almost everywhere, and the former light colour scarcely to be seen. *Red*, cocks.—First-and-cup *Royds*, the deepest red, and very fine *Jacobin* points; second, flights lower down than I like to see. This class a good one; very highly commended, highly commended, and commended abounding. The same may be said of the *Red* hens. *Yellow*, cocks.—First, second, and third, Hardy, Fulton, Swallow, happened to stand next each other. How often shall we see three such birds in adjoining pens? *Yellow*, hens.—First a fine ype of bird in eye and down face specially, not the Tumbler beak, as too often, but down beak, which gives the finish to the whole, hood, chain, &c. *White*.—Here was an advance, fifteen birds where three used to be. Some, I fancy, are crossed with *oreign Owls*; but none more exquisite than a good White Jack with pearl eye. First, second, and third very good. *Any other colour*.—Chiefly Blacks, some a little coarse. Two attempts at Blue, one an utter failure, being three-quarters of a German Toy; the other very fair but large. Please, D. Hicks, go on with this colour.

FANTAILS not so numerous as of old. Cocks.—These birds ought to be put in the judging pen before a decision is arrived

at; second better than first to my mind, the first being over-heavy and no motion. The first hen thoroughly good. *Any other colour* brought some interesting birds, perhaps the largest number of whole-coloured birds ever seen. First a Blue, with beautiful head and neck; third a Saddle-back, a capital colour.

NUNS.—Alas! alas! so few, so poor. Surely some fancier will earnestly work-up this fine old Toy. Only seven entries and only two good birds.

No alas! to be added about the TRUMPETERS, which came next. Eleven birds, and all good, some first-rate, as Mr. Lederer's and Mr. Hutchinson's.

ENGLISH OWLS fifty-eight, FOREIGN only ten, and yet there were fanciers who a few years ago wanted to extinguish the English Owl altogether. One thing must be said in fairness, that in quality they were both good.

The TURBITS were excellent and numerous, and

MAGPIES seem to continue to be attractive to many, and why not? Contrast of colour is always pleasing to the eye, particularly if the line of division, as in these birds, is a sharp one. Black, Red, and Yellow won in their order.

I think if judges had been more fair to Red and Yellow Nuns, not always giving to the Blacks, they, too, would have appeared in the show pens, for there are good birds in lofts in England.

The ARCHANGELS are falling off, and owing to the partiality of judges only one colour is shown; the light orange, a very telling colour, now not being seen. This also a pity.

RUNTS have revived and increased from three to twenty-three pens. Well done, good quiet old giants! I am glad you will not be put down by the spirit dwarfs. Ten out of eleven cocks noticed. There's for you!

The FLYING TUMBLER class brought some very good birds before the eye of the public, a fine Black Bald of Mr. Wood's being first; then there were Yellow Mottles, Black Mottles, and Red Mottles. Among the last a fine highly commended (3693) appeared, indeed the whole class (fifteen in number) was worthy. There ought to be twice as many; but mind and do not let them approach in beak too near the Shortface.

ANTWERPS.—The useful—i.e., the Homing birds, were very numerous, the fancy birds fewer.

With the ANY OTHER VARIETY class I must own to a feeling of disappointment—only sixteen entries. First Red Priests of good colour (Mr. Bryce's); second Frillbacks, third Suabians. A poor class, poorly filled.

The SELLING CLASSES.—Useful but not ornamental, but meet a want—namely, the want of those who wish for birds of small price but not necessarily cheap. This class reminds me of the home for lost dogs; you give but little for a pet, and it may answer or—otherwise. No warrant given.

BEST COLLECTION OF FOUR PAIRS OF PIGEONS.—These classes have increased greatly, and in former years were highly ornamental and well seen, being placed under the dome, and their handsome large cages crossing the ends of the other rows seemed to complete the Show, binding all in together. The cages so large and ornamental, and green-baize-floored, were highly attractive to strangers, the birds looking so well in them. Now this year all has changed much for the worst. Room being wanted for the visitors to examine the Chrysanthemums, these cages were actually put above the poultry pens and their whole beauty lost, and the birds too high up to be seen. I venture to think that at least one row might have been in the old place and space enough have remained, and I trust that next year this or some better arrangement will be made. In the first cage were shown not less than two varieties, excluding Pouters, Carriers, and Tumblers. First-and-cup (Fulton), Yellow Jacks, Owls, Turbits, and Barbs. In the third-prize pen were some good Scandaroons. The collections of Carriers, Pouters, and Tumblers were scarcely up to the mark, but Mr. Maynard's were grand. First-and-cup, 3893. The four birds of one, or any varieties, to be shown in a pen, brought nearly thirty entries. Black Magpies first. The four-pair pens are much the most interesting, and when each pen contains a pair of four different varieties the interest is much increased.

Such was our great national Show. Next year I hope that no distinguished fanciers will keep their birds at home. All the best should be at the Palace, and by-gones had best be by-gones. The judging gave satisfaction to most, and the Pouter judging to all (unsuccessful exhibitors of course not reckoned). I would in conclusion make a few remarks—thus on Tuesday the cards were not up till a very late hour, on some cages not at all. This was not the fault of the Judges, but of the clerks whose business it was to write out the awards. This should not be. Visitors who came for only one day had to leave without knowing whether their birds had won. The cards were not up for hours after the judging was over. One great improvement was the publishing a catalogue with the awards on the margin of each page, instead of some wonderfully puzzling separate issue as in former years. Though the new plan necessitated in some cases buying a second catalogue, yet better spend another shilling than have a loose unnumbered list to which reference had to be made. I hope the new plan will be adhered to.

The absence of mismarked Pouters was a good riddance; they are birds for the loft like stock birds. But I should much like to have seen a class for standard Pied Meales, for it is a beautiful colour, with proper bars, &c., not washed-out Meales, and it is a very old colour. Then Meales are cheap, so the poor fancier could have a chance, and in shape the birds are often elegant.

One met at the Show with pleasure old acquaintances and made new friends; saw *in propria persona* those known before only by letter. There were enthusiastic new fanciers come for a first sight of this great Show, and old fanciers whom its birds made again enthusiastic. Grave men looking delighted, fair ladies whose cheeks glowed with pleasure. "There were," says old Grumbleton, "those horrid cocks everlastingly crowing, I suppose." I answer in the words of a lady, that under this high crystal roof "the crowing sounded like a band of music." There's for you Mr. Grumbleton, please to grumble no more. I have spoken of the good judging—all things are not good at the Palace. Having a spare half hour I tried every weighing machine I could find, sat down, smart boy handed the card with correct (!) weight on. Every machine gave a different weight, and not one of them was correct. This is a little thing, but a lie even in little matters deserves exposure. I dare say the weights had never been touched since the Palace was built; hence they are all light with wear. It's a grand old place though, in spite of weighing machines, an historical place. 'Tis the best sight we have to show to strangers, and ought to be adopted by the nation, and a part rebuilt and everything kept in repair. It awakens in one's mind different feelings to any other place. Paxton, Chatsworth, Hyde Park in 1851—grand opening—high hopes in regard to art culture, not, alas! realised, for the courts are by most unnoticed. But there are the gardens always grand either with shrubs or flowers, or both, but never to my mind does the inside of the old Palace look better than at our annual and national (make it more entirely national, good fanciers) Pigeon Show. The elegant birds of various colours form a soft moving carpet in the transept. Even the Pigeon-ignorant like to walk through the rows and admire, and may they increasingly admire until they learn the pleasure of being Pigeon fanciers.—WILTSHIRE RECTOR.

#### POULTRY.

**DORKINGS.**—We have perhaps seen one or two finer shows, still on the whole there was a grand collection of birds, and the standard was high throughout all the class. First in Dark cocks was a fine bird in size and shape, capital in colour and general condition, but he had too much white in his tail, and was shaky on his legs—a serious fault. Second was out of condition, and carried his tail too far back, but had beautifully white feet. Third a big bird in fair condition, but gouty. The class for hens was in our opinion the best of the Dark Dorking classes. The cup went to a bird quite to our fancy, moderately dark in colour, large without being coarse in bone, and in admirable condition; second, a fine hen with a broad tail, a point which we admire, as such birds breed cocks with good sickles, she was not quite so white in feet or so blooming in condition as the first; third, a very long hen, the shape for a stock bird, lighter in colour than Mr. Burnell generally shows. Various other hens were well worthy of honour and remark. We specially noted 16 (Mrs. Radcliffe), a good white-footed hen; 20 (Walker), very large but with a double toenail, and a little gouty; 26 (Burnell), very rich in colour; 29 (Mr. Sapwell), very white in feet, and light in condition though small. As a class the hens were in good condition, and we were pleased to see prizes again going to hens of moderate darkness in colour, for we believe that the prevalent footy feet have some connection with very dark plumage. Cockerels were in our opinion the next best class to the hens, and the cup went to a grand and massive bird, lightish in colour with perfect comb and fine broad black sickles; his only fault is that his fifth toes does not turn up. Second, a capital bird, dark in colour with white in tail; his feet are good, but he has not the breadth of the cup bird. Third, a blooming dark cockerel again. Fourth, a well-shaped dark bird with white in tail and bronze on wings, his feet very white. Fifth, a good bird all round, with brown on the wing again. There were many other capital birds among the forty-six. We noticed 33 (Ellie), a tall white-footed bird, as yet a little raw; 36 (Lord Turnour), a thorough Dorking in shape; 59 (Beachey), a big dark bird, spurs not well inside; 68 (Beachey), good, but white in ears; 73 (Rev. H. F. Hamilton), a pretty bird. The pullets, thirty-five in number, we did not think equal to the cockerels. First was not in good condition, and we did not agree with the award. Second a very dark bird with very white feet, but with no other merit. Third, a moderate bird, rather dark in feet. Fourth, a decidedly fine pullet. Fifth, good in frame. We liked 86 (Burnell); 93 (Parlett), a capital bird all round; 99 (Barker), though her feet are too dark; 102, a big bird (the Duchess of Hamilton); 111 (Lingwood), large in frame.

**Silver-Grey** cocks were but a small class. First, a very small bird, we supposed his style procured him his place. Second, a fine bird but with white in sickle, and one spur not well inside.

Third, the largest bird in this class, but not well through the moult yet. The first hen is a magnificent bird, capital in colour and square in body. Second a much smaller bird, an old-fashioned Dorking in form. Third, a capital match for the first in shape, but very inferior to her in colour; 123 (Cresswell) the cup-winner at various previous shows, we much preferred to her owner's prize bird. Cockerels.—First a noble-looking bird with good comb. Second a well-shaped Dorking, but not in the condition of the first. Third a promising young bird, but very inferior to its owner's highly commended one. Pullets.—First a beautiful pullet all round, white in feet, silvery in general colour and deep in breast colour; she was claimed for £12, as was her owner's unnoticed pullet for the same sum. We have never before heard of two Silver-Grey pullets fetching so large a sum as £24. Second, a fine large pullet, a little mixy in colour. Third a very fair bird; 146 (Plummer), good but dusky in feet; 148 (Burnell), large, but in the moult.

**Cuckoos** were shown in pairs; there seems at last to be some improvement in this breed. First were a pair of chickens good in all points. The second pen contained a very dark cockerel, good in shape, but with an ugly double spike behind his comb. Third, old birds, the cock rather coarse but very large; 169 (Young), cockerel good in comb and worth notice; 170 (Lady G. Gordon), very young and promising chickens.

**Whites** were not quite so numerous as last year, but good and well shown. In cocks first was a young bird, second at Oxford, when we especially mentioned him as admirable in shape; unfortunately he is turning yellow. Second, a fine cock, not through the moult and with the yellow sap still much in his feathers. Third, a small cock but very white. Hens were a better class than the cocks. First-and-cup, a lovely old bird—the cup bird too last year—we never saw a better. Second, another grand hen, a good match for the first. Third, a pullet upon which we remarked favourably at Oxford; 189 (Darby), square and good in shape; 192 (Hayne), also a good Dorking. There was a five-guinea Selling class containing some very fair specimens, but such bargains are generally delusive.

**BRAHMAS, Dark.**—First, a grand old bird, good all round, the one of which "W." spoke so highly in Mr. Lingwood's "Basse-cœur." Second, a magnificent bird in capital condition with good broad hackle stripes, but disfigured by a bad comb. Third, hooked, not very good in colour, but with attractive wing-bars. Fourth, a broad, deep, and massive bird but in poor condition. Fifth, a small fairly-shaped bird with a horrid comb. We certainly should have put Mr. Ansell's bird about third in the list, for he is a grand fellow all round, though certainly at present out of condition. In hens the cup went to an exquisitely pencilled bird, but rather brown and terribly scaly in feet. Second, a fine bird, dark all over, with rather blunt pencilling, a little deficient in leg-feathering. Third, better pencilled on the breast than elsewhere. Fourth, too heavily feathered, with beautifully pencilled breast, but a little mixy on the wing. We thought 554 (Newnham & Manby) and 564 (J. F. Smith) two very good hens. In cockerels Mr. Lingwood is in his old place; the cup bird is one of the real Creeping type, somewhat hooked and high in tail, but with small highly bred head. Second, smaller, but in point very even with first. Third, a severely pocked bird. Long before the awards were given out we exclaimed on casually passing this bird at his plucked appearance, for the business had not been artistically done, and the exposed white under-down easily betrayed it. How the Judge did not at once find it out we cannot comprehend; subsequently on a protest being entered against the award, the bird was disqualified and the prize forfeited. Fourth, a little long on leg. Fifth, very peculiar in tail. Sixth, a well-shaped bird for breeding, but too yellow. Seventh decidedly bad in comb, otherwise a good bird, well grown tail and good orange legs. Beyond the winner there were very few we much cared for in this class. The mottled-breasted cockerels (when really mottled) were as last year decidedly inferior in the points to the Black-breasted birds; their price seemed in most cases low. First was a capital bird with curling hock feathers, but not really mottled. Second, prettily mottled. Third, a fine bird; 600 (Gamer), unnoticed and good. Pullets.—We must say we did not think the cup-winner by any means the best bird in this class; she is certainly good in shape but very small; her pencilling is really black, and ground colour white. Second, a fine large pullet, remarkably well-pencilled on back. Third, hooked, very dark all over with good breast. Fourth, slightly hooked, with silver ground colour, and very pretty round pencilling, rather brown on the back. Fifth, neat small pencilling but rather light on breast. Sixth, evenly-marked. Seventh, splendid in pencilling but rather narrow in body, and with a slipped wing. There were many remarkable birds in this class besides the winners; 643, very highly commended (Lingwood), well pencilled but a little leggy; 650 (Lingwood), spoilt by different pencillings being combined; 654 (Pearson), should have been noticed; 655 (Peake), very pretty; 673 (Peake), very dark and good in breast; 682 (Newnham & Manby), fine in shape; 694 (Mrs. A. Tindal), wonderful in pencilling, but almost devoid of leg-feathering.

**Lights.**—In his place of last year was Mr. Horsfall's grand old cock, looking as well as ever in all points, but much larger; he is now really a grand bird in size, as well as almost perfect in every point required. Second, lovely in colour and good in shape; we thought he had a suspicion of a loose wing. Third, too high on leg, but very fine. Fourth, the cup cockerel of last year, his high comb is his only fault. Fifth good in shape, but neck hackle full of sap. 725 (Percival), would have shown to better advantage, if not next to the cup bird; 727 (Haines), had good hackle-marking and foot-feathering but no shape; 737 (Horsfall), had a well-bred Brahma head.

In hens the cup bird was very nearly faultless, a little too much hooked. Second very good, not quite such a pure white as first. What a grand pair they would make! Third a little mossy in hackle. Fourth by no means a remarkable bird. Fifth a little sandy in tinge, and too white in tail. 740 (Petter), good but short of feather on leg; 750 (Pitt), deserved notice; 756 (Sambrooke), a capital hen in all points but foot-feathering; 758 (J. T. Smith), deserved notice; 767 (Lucas), capital in neck hackle; 768 (Bird), not large but pretty. Cockerels were an immense and magnificent class of seventy-five. The cup was a good award. The bird is very large and white. We thought his hackle a little twisted. Second almost devoid of neck marking, but finely feathered and with a beautifully laced tail. We must say we thought this award a mistake. Third very young and promising. Fourth small but shapely. Fifth small too. Sixth rather wanting in cheek. Seventh might have been higher, his only fault being slight yellowness. We cannot conceive why Mr. Borrow's bird (831) was left out, the only explanation can be, that being in an end pen he had the full sunlight upon him and so appeared tinged. We fancy he is the Oxford cup bird, and a noble bird he is too. The pullets numbered eighty-eight. One of Mr. Dean's birds which have caused so much discussion was deservedly first. She might be a little lower on the leg, otherwise she is perfect. Second would be a most useful bird in breeding, but her neck-hackle is too black. Third high on the leg, but may settle down into a fine hen. Fourth a little small but good all round. Fifth short of leg-feathering but fine. Sixth very small and narrow, but good in colour with beautiful neck-hackle. Seventh a big pullet, good in shape, a little wanting in neck-hackle. We thought 848 (Dowker), deserving of a place. 888 (Horsfall), fine in form, a little too dark in fluff. There were a few poor birds in this class, but nearly all those noticed would have been winners a few years ago.

**HAMBURGERS.**—In *Golden-spangled* cocks the first bird was good in comb, with heavy spangling and splendid in colour. His carriage is fairly good, though we have seen more elegant birds. Second good in comb and lobes, but not a sprightly bird. Third apparently doctored, and not good in comb, with lovely white earlobes. 1183 (Duckworth), a pretty bird with an honest comb. 1188 (Long), has many good points, but was apparently suffering from the new disease. The first hen was a beautiful bird, her spangling of moderate size throughout and evenly distributed, and her ground colour very rich. Second in fair condition, her moons larger and not quite so even as the first. Third an old bird with small and even moons, but touched with white here and there from age. We thought the *Silver-spangled* cocks a poor lot. First with comb very flat and suspiciously smooth on the top, his spangling moderately deep, carriage indifferent. Second a good bird all round save in tail, which has some ugly black splashes on it. Third we liked the best in the class. His carriage is good and his comb honestly so. We suppose his spangling being rather smaller than the present fashion pulled him down. The cup for hens went to the first *Silver-spangle*, a lovely pullet in blooming condition and evenly marked all over. Her neck-hackle stuck out oddly. Second more to our taste in marking than the cup hen, so pretty and accurate though not large in her spangling. Third large in moons, not very good in shape. We liked 1226 (Park). We much liked the first *Golden-pencilled* cock. It is refreshing to see a naturally-shown bird, and we heartily welcome a new exhibitor of the breed. The bird was, of course, run up at the auction, being only priced at five guineas. He is a good chestnut colour all over, moderately dark in neck-hackle, and attractively edged on tail. Second small elegant bird, very dark. His comb had apparently been a little improved. Third a cockerel with bronze sickles and indifferent comb. We much preferred 1235 (Tickner). The first hen very black in barring, but slightly coarser than the now generally admired type. Second rather broad in marking. Third not remarkable save for breast-marking. 1250 (Tickner), had small even pencilling, but not a clear hackle. 1254 (Judson), the richest ground colour in the class, but mossy in tail. The cup for the best *Hamburg* cock went to the first *Silver-pencil*, a lovely bird with exquisitely laced tail. We have before admired him. Second not very clear in colour, with a natural comb. Third very young and promising, too white in tail. *Silver pencilled* hens were very few. The first an evenly-marked bird. Second and third only fair.

**Black Cocks.**—First was a good bird all round save in comb, which had been unmistakeably doctored. Second looked very

good in colour, but had the advantage of a corner pen. We much liked the third, a purplish bird in tinge with good comb. Ten birds in this class received high commendations. We liked 1283 (Serjeantson); 1288 (Long); 1295 (Robinson). The *Black* hens were, unfortunately, alone of all the *Hamburgs*, placed in a bad light in an under tier. First was pretty in comb and shape, and small. Second a larger bird but good in style. Third rather plain in comb, seemingly a good colour. 1299 (Serjeantson), was to our eye the prettiest bird in the class, but of their colour it was impossible for anyone to judge in such a position.—C.

**COCHINS.**—These made wonderfully good classes. In old *Buff* cocks the first-prize bird was very large, and broad, and good in colour; the second also good, but immensely hooked; third an excellent bird all round, but not quite ready. In hens the winner was pale in colour and had her wings very untidy, or else was large and square; second a good hen, but we liked the third as well as any; she was good in colour, large, and deep, and held the same position last year. In cockerels we greatly admired the cup bird; he has not too neat a head, but his shape and colour were both good. Second and third two well-grown chickens of even colour and of pretty shape. Pullets were capital, and one or two—e.g., 295 (Lady Gwydyr), 296 (Darby), and 303 (Burnell) seemed worthy of higher cards than they received. The winner was rather spotty in colour and had ugly wings, or else was well proportioned; second was in all respects a superior bird. The third old *Partridge* cocks were all good; the second had a crooked toe, or else was of capital shape, while Lady Gwydyr's was to our mind a grand bird, just a shade too dark. In hens a fine bird was first, second a good bird too, third an immense hen, but not quite distinct enough in markings, but her shape and fluff were very grand. *Partridge* cockerels were, perhaps, one of the weakest *Cochin* classes. We liked very much pen 339 (Acton Tindal); he is young yet, but has much quality, and promises to make a good bird to breed from. The first was not very black in fluff, or else of light colour, and will improve yet. Pullets were moderate, and we thought all rather too red and rather wanting in markings. In *White* adult cocks the cup bird (Boissier) was snowy white and well shown; second was the first *Circencester* bird, and we do not like his comb; third was ugly in shape, but good in colour. We liked very much indeed pen 369 (Bamford). He certainly is not well through yet, but is immense in frame, very white, and heavily foot-feathered. In the hens we noticed many superb birds, as good as we ever saw them. First was of grand shape, fluff, and colour; second rather pale in comb, or else of good shape; third a large and useful hen, good in colour, comb, and feet. There were also other good hens shown by Messrs. Boissier, Tindal, Bloodworth, and Percival. Cockerels were only moderate, except the first-prize bird, which was the Oxford cup cockerel, but now is losing some of his pure whiteness. He is a grand chicken in every way, and we hear goes to a new master after Birmingham. Second stylish, but rather high in tail; third poor in colour and of not much shape. 400 (Copplestone) very white, but too *Pointer*-like in legs. In pullets the first and second were both good; for third place we preferred pen 411 (Turner). She is a large bird of good colour. Adult *Black* *Cochins* were rather a seedy lot; all looked untidy on the legs, and seemed to want more time. In cockerels we liked the winner best, then pen 437 (Storer), and then 443 (Lady Gwydyr). In pullets the first was good, and the second also. We much liked, too, Mr. Chawner's and Mr. Cook's.

In the £5 5s. Sale class there was a good hen in the first-prize pen of *Partridge*, and a good cock in the third-prize pen of *Whites*, but he had a crooked beak. The rest of the class was not up to the average of former years in our opinion. As for the *Langshans* it was a ridiculous farce to give them classes, and each pen seemed to point out the absurdity more, for many of them had really good *Cochin* points. They appear to be only the refuse and weeders of *Cochins*, and the second pen we know was this, for the owner had told us weeks before he intended entering such. "*Langshans*!" said an old *Cochin*-breeder, "call them '*Long Shins*.' We do not think our friend was much out. It is a pity such classes for refuse birds should be encouraged; we perceived nowhere the "*Wild Turkey*" blood in any bird.

**MALAYS.**—Sixteen pens of capital birds put in an appearance. The first very large and very shapely, but not in feather. Second was a good cockerel in every way, and we still think there is more growth in him; his mate was good and had capital carriage, being, too, of the colour we so much admire. The third were very tall, and good in condition and feather. The whole class was the best of the breed we ever saw. Miss Brooke sent a good pen in excellent plumage.

**SILKIES.**—These made a small class. Five pens were really good, another contained single-combed birds; and the other, the third-prize pen, was a hideous pair, yellow and green legs and red combs. We cannot imagine how the Judge selected such a pen. The first were rather large and very white, but too heavily feathered for our own taste; second a good pair all round, only

the cockerel a little too red in comb. They were well washed and in pretty feather.

**POLANDS.**—All colours came well to the front, and we saw Mr. Boothby sent some *Buff Chamois*. We like them much, and hope he will continue to work them up. The cup went to a *Golden cock*—light, and large in crest, though we preferred, as we believe did many more, the unnoticed pen of the same owner. Golden hens were all good, and we think they were well selected. Polanders seem to be increasing in favour. In *Silver* cocks the first was grand in crest and attractively marked, shown too in good condition and feather; second also splendid, but wants a week or two more to make him perfect; third a good bird in every way. Lady Dartmouth's bird, bar his bad colour on his back, was as good as any bird for crest and markings. The first and second *Silver* hens were two grand birds, as good as we ever saw any, and we cannot imagine there can be any others of the colour to beat them. In the two next classes were the *White-crested Blacks*, a breed which was once so near extinction, and now is "blossoming like the rose." They numbered only one short of the *Silvers*, and were of splendid quality. We know one or two thought the first bird should not have won in cocks; but we did not, and we walked up and down the class before the cards were up, and still "spotted" him. His crest is not through, it is true, but his hackles, lustre, and condition are things to be remembered. The second was a grand old cock with very white crest. For third place we almost preferred 1608 (*Lias*) or 1604 (*Darby*). In hens the first bird is a gem. Such a pullet, for she was a pullet, if she lives to be a hen must be a marvel, for she is that now. Second a grand hen, very white, and very good. Third a very pretty hen in every way. 1614 (*Darby*) a grand hen, known to be eleven years old.

**LEGHORNS.**—Well done the Club! twenty-eight pens of *Browns*. Were we members we should want the *White* subscribers to pay a double subscription, as the Club must have often to make up their deficit. *Brown* cocks alone numbered as many as the *White* cocks and hens. We think the condition of the first cock in *Browns* won him the place, for in head we liked the second best; but here, as in *Houdans*, we fear there is often much "topsy-turveydom" in judging. In hens we certainly liked the second best; her shape, colour, ears, and bloom we thought all superior, though the first was by no means a bad one. Third we fancied was rather small, or else pretty in head and comb. In *Whites* the first cock was very neat, and in his place; second also good all round; third rather bad in colour. The hens were good, and we can imagine them looking well on a grass run. They seemed to be well placed, and all looked in good condition, and as if in laying order.

**SPANISH.**—In adult cocks the first was large in face and good in comb, and was well selected, as appeared to be all the *Spanish* winners; second also good, but once or twice when we passed him he looked rather mopish. In hens the first was a fine bird, good in comb and smooth in face. One or two other good hens only want more time, as they had all the quality about them. The winning cockerels were all fair birds, but they too at times looked a little tucked-up by cold. We do not know if they wanted more food, for we heard many say that the birds were not given enough; certainly they did seem ravenous, and especially on the last day. In pullets the first was certainly in the best condition, and was well selected; and we heard many admire this cup bird very much. Second a good bird, but a little untidy in face; third not so neat as first.

**GAME.**—The first *Black Red* cock, which also won the cup, was a grand bird, and had colour, shape, and carriage; second also very good in head, and of capital colour. In cockerels we almost preferred the second bird, for his head points seemed better; but the first had perhaps the advantage in colour. In hens all the winners were good, and seemed to be well chosen out of thirty pens of fine quality. In *Brown Red* cocks we admired the first very much; he has good colour and good limbs. Second had rather an ugly tail, or else was capital in other respects. In cockerels the cup bird is not yet in full show; he has many good points, but we believe one or two *Game* breeders preferred the third-prize bird. 1406 (*Martin*) we were told was the champion *Islington* winner. He is a grand chicken, and has very fine carriage and colour. In the next class pullets won all the prizes; all good, and all well chosen. In *Duckwing* cocks the cup bird is a beauty, in fine feather of good colour; second also very good, and closely coming up to the cup bird. A grand pullet for colour and shape won in this class. In *Piles* an old yellow-legged bird was first, and second a willow-legged one; third a *Black*. In hens all the prizes went to *Piles*. The third we much admired as good in colour and shape. In the £5 5s. class *Brown Reds* won first and second, and good *Duckwings* third, which might well have come in between the *Brown Reds*. On the whole—i.e., all told—the quality was very good indeed.

**THE VARIETY CLASS.**—This was an excellent collection, and created much admiration among the visitors, who always seem

to enjoy a medley. First large *La Flèche* chickens; second good *Cuckoo Cochins*. We noticed Mr. Montresor's real *Indian Game*, and a beautiful *Sultan* hen in Mrs. Christy's pen. A good pen of Miss Palmer's *Dumplings*, and a fine pen of *La Flèche* (*Upsher*) we also saw. *Bantams*.—These classes were all good. Among the *Game* the cup *Black Red* cockerel and cup pullet were both very stylish and pretty, with good carriage. The *Brown Reds* too were a capital lot. We much liked, too, the cup *Pile* cock and the first *Duckwing* hen; the latter especially was very clear in colour and neat in shape. *Black Bantams* were a very fine lot, and we quite liked the winners. In *White-boots* colour seems to have been thought of before boots, in which the winners were excellent. 2337 (*Boissier*) yellow-legged, but very heavily feathered; 2340 (*Woodgate*) empty, the birds not having come back from *Cirencester* through railway carelessness; 2341 (*King*) very good indeed, but the cockerel had recently lost a serration of his comb. Sebrights were admirable, but of the *Silvers* we liked 2344 (*Leno*) best, the cup pair not being quite free from a cloudy lot on the silver part of most feathers; second pretty *Gold*s, of a deep shade; third very pretty *Silvers*, with neat lacing. In the *Variety* class excellent *Black-boots* were first, very lustrous in colour, and in fine condition; second pretty *White Rosecombs*; third *Japanese*; 2362 (*Walton*) good *White Rosecombs*; 2358 (*Davie*) *White Frizzled*, very beautiful in colour and feather, but the claws did not match in number, neither was the hen's comb at all pretty or shapely.

**WATERFOWL.**—*Aylesburys* were capital. The three winning pens all good. In *Rouens* the first drake walked in easily. In *Ducks* the winners were well coloured, shapely, and massive in appearance. Mr. Parlett also had a good bird in pen 2483. As for the *Blacks* we will not pretend to judge of them. The awards all seemed to be an upsetting of previous decisions. We fully believe nearly every exhibitor thought his own birds the best. Certainly the colour was generally very fine, but we have seen smaller birds: still, we are no advocates for their being so tiny, and always prefer colour. We admired the cup pen and thought they well deserved a place, but whether before Mr. Sainsbury's, or Mr. Brown's, or Mr. Malden's, is an open question.

In the fancy *Ducks* we thought several out of feather, still the whole class was highly commended. First went to *Variiegated Kasarkas*, so we were told they were named, others call them *Paradise Ducks*; *Spotted Bills* took second, and *Mandarins* third. Mr. Leno showed a choice pair of *Brazilian Teal*, and Mr. Booth good *Mandarins*. In *Geese* Mr. Fowler again won the cup. We noticed a pair of curly *Sevastopol*, which seemed to require a "tub." In *Turkeys* we heard grave doubts as to the age of some of the specimens, one exhibitor positively affirming that a bird had won as a "poult" for two years in succession. If so it is a pity such things should be; and as the matter lies with the Judges they alone can prevent the occurrence. All the classes were well filled, and the birds exhibited by Mrs. Wykes were undoubtedly "poults," and well-grown birds too.—W.

### THIS AUTUMN'S SEASON FOR BEES.

In the *Journal* of November 9th I see that Mr. Hunter speaks of this autumn as an equally unfortunate season for bees, though in a different way, as the last. My experience in both cases has been exactly the reverse, except only as to the poverty-stricken condition of the hives last autumn. My hives last year were far less than usually populous, whereas this year they are splendidly full of bees. The cause of this difference, however, is really the same in both cases. Here our honey season, though good for us, would doubtless have been considered a poor one in the more favoured north and east, and perhaps the south of England. Hence our bees, not being overstocked with honey, have been breeding unusually well, and give good hope of thriving next year, supposing all other things to go well.

Once only have I known such a splendid time for ivy, both in respect of honey and pollen. Day after day the bees have been at work early and late, with the same loud humming going on as in summer time, and I see honey glistening in deep open cells all over my hives, not, however, in such quantities as to prevent the queen laying eggs, as witness the young *Italians* issuing from the hives every fine day. One or two hives I have fed slightly though continuously, just to stimulate them; but I do not find that those I have not fed have been less active in breeding or honey-gathering. I am, therefore, remarkably well off as to my prospects for next year.

I am pleased to observe that Mr. Hunter has carried out this year what I have more than once advocated in this *Journal*, I mean the absolute and entire plunder of the honey in the hives, and the subsequent continuous feeding-up of the bees during the autumn months. The result given by him is exactly what I have predicted, as I have also myself experienced—namely, "teeming populations and abundance of brood in all stages." Nothing can be desired better, if to this be superadded a well-provisioned hive by continuous feeding.

In the belief that bees are best left to themselves after *Martin*-

mas, I have this day (10th November) anticipated the saint's anniversary by twenty-four hours, and packed-up against rain, and snow, and frost, all my exposed hives, covering them up with every warm thing I could lay hold of, chiefly old felt druggot, and protecting all with boards and tiles. They look queer; but what of that? as they are out of sight in a sheltered corner of my garden. There let them rest till spring suns once more shine.—B. & W.

### THE WAX MOTH AND FOUL BROOD.

WAX MOTHS and the disease of foul brood have been rather prevalent this year. We never noticed so many wax moths flying about hives as we have seen this season, yet we have not found the combs of healthy hives injured by them—*i.e.*, by their grubs, though these have been frequently found on the boards of healthy hives, generally where the inside edges of the hives touch and rest on the boards. The grubs of wax moths are covered for a time with a downy or wool-like substance. While in this state, and while growing into it, it is not easy to determine how and by what means they are fed, for the combs above them remain uninjured till the maggots begin to burrow amongst the cells, devouring the wax as they burrow. In eating the wax they leave the pollen, which falls as dust on the boards. The wax moth is a kind of small butterfly of a dirty white or creamy grey colour, and doubtless has a keen scent for wax. Last summer I placed a hive of combs in a hothouse and another in an open shed. The one in the shed was covered with a piece of cocoa-nut matting. Of course the moths could not penetrate the matting, hence they deposited their eggs in or on it. Soon it became one mass of woolly maggots. These were given to the hens before they began to feed on the wax. The combs in the hothouse were eaten by the grubs. I do not think that the moth does much harm in this country to healthy hives, but as it is sometimes hatched in all kinds of hives it is well to examine them frequently and keep their boards clean.

Foul brood was found in many hives this year. I remember no season in which it was so prevalent. The cause of the origin and progress of this malady is still veiled from the most advanced and enlightened apiarian. Every attempt to investigate and explain the mystery of foul brood has been unsuccessful and unsatisfactory. The best that has been done by way of explanation has consisted merely of guess work only. My own guessing has gone in the direction of imperfect feeding or improper food. One thing is certain—there is no cure for the plague of foul brood but the removal from the hives of the diseased combs (plague spots), or, better still, the removal of the bees wholly from their lazar-houses into clean hives. Hives affected with this malady never prosper, but invariably become worse and worse by the multiplication of diseased cells, the stench of which becomes unbearable, often causing the bees to abandon their hives in utter despair and go off as swarms; and sometimes they leave the foul combs and cluster on the outsides of their hives or underneath the boards and there build combs. The existence of foul brood in hives may be discovered by the shape of the cell lids covering it, by its smell, and by the conduct of the bees.—A. PETTIGREW.

### BAR HIVES.

In reply to the questions forwarded to me, the hives I use are after the Woodbury principle, 8½ inches deep, 14½ inches square, inside measure; these hold ten frames. Some I have just made with fourteen frames, which I shall try next season. A very large hive would not suit this locality, as it is only a fairly good one for honey-gathering. Your correspondent should be guided as to size of hive employed by the amount of pasturage for bees in his particular neighbourhood. Of course other considerations must also be taken into account, such as size of swarm, time of swarming, &c.; but by all means give the bees plenty of room below if large supers are to be filled, and have that space well supplied with combs and a reasonable amount of food early in the season by gentle feeding, and, if possible, by the insertion of empty combs where there are vacant frames, so that the glut of the honey season may go to the super. All my bees are the common English kind. I hope to give the Ligurians a trial next season.

Your correspondent, "J. H. E.," asks whether any brood was reared in my supers. Among thirty-three supers only two had a few cells at their base in which the queens had deposited eggs. One of these had but perhaps twenty cells so occupied, after which her majesty had retired; but in the other (a very large bell-glass, which I had intended for competition) the whole of a central comb was appropriated to breeding purposes. This super I had to break up and use at home, employing the dark comb in filling a frame for another hive. The queen does not enter one out of twenty supers if the slits for the entrances are made towards the sides of the hives, not over the central combs. This next season I shall work most of my supers upon sheets of

perforated zinc,  $\frac{1}{4}$ -sized holes. Mr. Cowan's grand supers were so worked.—P. H. PHILLIPS, *Offley Lodge, Hitchin.*

### OUR LETTER BOX.

PRODUCTION OF EGGS (*W. O. M.*).—Truly those who write poultry books have much to answer for. If you are never satisfied till you obtain 150 eggs from each hen you will lead a worrying life. It is not to be done. We do not tell you it never happens—we know that it does, but such examples are rare occurrences. The great advantage of keeping pullets is, that they lay in the winter if they are so hatched as to arrive at maturity in that season. There is no winter-laying breed; it is a question of age. If birds are to lay at six months old, and the eggs are wanted in November, preparation should be made early in May, and pullets hatched then put aside for the purpose. By such provision eggs may be secured through the winter. It can, however, be done only with pullets. After they have become hens they follow the ordinary course of nature, and lay in their natural season. As a rule the older hens are the worse they lay, and if eggs are chiefly wanted we advise you to keep no birds more than two years old. There is no objection to your feeding, only we think you may advantageously substitute ground oats or barley meal for the morning feed of Indian corn. We advise you to discard your hens of 1874. You will sell them easily. If you want a regular and full supply of eggs you should be getting them now from pullets hatched in April and May, and if the remainder of your stock was made up of last year's pullets, they would begin laying when the others left off. You will not induce laying by over-feeding; you will make fat, which is a great hindrance. We do not care for cinder ashes; but it is essential the birds should have dry sand or road grit to dust in. It keeps them free from vermin, and no fowl is healthy unless it is clean. We believe you may keep your cock till he is three years old—not longer. We do not quite agree to your theory as to the influence of the age of the cock on the number of eggs. We do not believe it has anything to do with it.

CRYSTAL PALACE POULTRY SHOW.—In the Trumpeter Pigeon Class, Mr. J. Lederer, Liverpool, informs us that he won the cup and first prize, third prize and highly commended, with three Trumpeters.

ALEXANDRA PALACE BEE SHOW.—We have a letter for T. W. Cowan, and one for Mr. J. M. Hooker, but do not know their directions.

WEIGHT OF HIVES.—MR. HALE (*J. H. Eldridge*).—Some bee-keepers weigh their hives with the boards, and some without. The weights given by Mr. Pettigrew always include the hives, and sometimes both hives and boards. Ordinary hives weigh about 5 lbs., and boards 4 lbs. each. Mr. Hale has been written to, but no answer has yet come. In early summer he informed us that his large stock of hives (about one hundred) had been reduced to twenty-eight stocks, chiefly by deaths. Whether he tried the experiment promised or not we cannot tell, but fancy that the deaths in his apiary interfered with his plans.

### REMARKS.

- 15th.—Rainy morning, fine afternoon, but foggy in the evening.  
16th.—Very wet morning; bright and sunny afterwards, and starlight night.  
17th.—Beautiful morning, but rather cloudy at times during the day; fine at night.  
18th.—Foggy early; rain commenced at 11.15 A.M., and continued at intervals all day.  
19th.—Fine morning; pleasant all day, at times very bright.  
20th.—Morning early fine; but rain began about 10 A.M., and continued more or less all day.  
21st.—Rather dull and damp all day, but not much rain.  
Remarkable change of temperature, especially at the beginning of the week. The mean temperature of the week has been nearly 13° above that of the one preceding.—G. J. SIMONS.

### COVENT GARDEN MARKET.—NOVEMBER 23.

A GENERAL stagnation is experienced in all departments of our Market, and prices rule somewhat lower. St. Michael Pines are again in the Market, and bid fair to be sold at prices this year which will fail to remunerate the growers. Kent Cobbs with a better demand are firm at last week's quotation.

From observations taken near London during forty-three years, the average day temperature of the week is 46.7°; and its night temperature 35.3°.

## ALTERATIONS.

HOW much meaning is attached to that one word it is impossible to say, and equally impossible is it to estimate the amount of labour which every year must be credited to the subject which it represents. When we think of the word—or rather the work which it shadows—we are constrained to think of the taste which is exercised annually—taste gone mad in many instances, possibly. We are reminded also of the changeful disposition of owners and gardeners, for certainly neither one nor the other can long remain satisfied without “making alterations.”

Alterations in the minds of some would appear to be the be-all and end-all of a gardener's duties. No sooner is a gardener, especially a young one, placed in charge of a garden than he must commence making changes. A hundred to one if his predecessor—however able he may have conducted his change—will be regarded by the “man in possession” as having been competent in his calling, and forthwith the weak points are paraded and every nook and corner is sought to give a handle wherewith to grind out a tune—a dolorous ditty—on neglect, delinquencies, and ruin which the new man is called upon to inherit. And now commences the great work of alterations. These may be necessary, or some of them, and they will look quite as well when carried out if unaccompanied by any running commentary on the shortcomings of someone who left them to be accomplished, and provided an opportunity for the operator of making himself famous.

In essaying the making of alterations it is always highly important that a full and proper understanding should exist between an employer and gardener. For the want of this necessary and proper agreement much unpleasantness has arisen in the past, and which has too often led to inconvenience on the part of the master and loss—serious loss—to the man.

Let it always be remembered that it is not sufficient for a gardener alone to consider that alterations are needed, and forthwith proceed to make them on the property and at the expense of another. The owner must also see the necessity of the projected changes and should give his sanction to what is proposed; then is responsibility removed from a servant whose care on ordinary matters of routine and his daily labour is sufficient for one in his position to bear. I allude not now to trivial changes which a man may make for his own convenience and the better performance of his duties, but to radical and fundamental alterations on which the owner of a garden very properly desires to be consulted.

The question now arises as to what must be regarded as a radical alteration. All alterations involving extra labour and outlay naturally come under this category, and especially so if the cost is not merely a “first cost” and then done with, but which may render further outlay necessary extending over an indefinite period. As a

general rule alterations when made in gardens involve additional labour being expended for some time after they have been done. That is a condition which requires serious consideration, for what may be considered a trifling matter by a gardener may be a vital point with the owner of the garden. Some there are who desire improvements rendering their grounds more picturesque and enjoyable, and who do not hesitate to allow any additional outlay which may be required as a consequence of any changes which may be made to effect that end, but the great majority are otherwise disposed. They do not feel themselves justified in sanctioning further expenditure, and would rather forego the pleasure of making improvements than incur the cost of them. When this is known—and there is generally no difficulty in ascertaining it—it behoves a gardener to proceed cautiously and not permit his enthusiasm, which is pardonable and even laudable in itself, from impelling him to a course of action for which he may have to pay the penalty at some—it may be not far—distant date. All alterations which have a tendency to permanently increase expenditure are decidedly of a fundamental character, and should never be carried out without the sanction of those who have to pay for them. Some owners of gardens are sufficiently candid to admit that alterations are desirable, but to that append a warning that if the grounds cannot be kept in order after the projected changes without further assistance the gardener will have to bear the responsibility. That is a difficult position for a gardener to be placed in, for the very wish of an employer will often tempt an earnest man to run some risk of his own welfare in order to meet the desires of his employer. A gardener in such a position must think intently over his project and make his calculations with great care lest failure ensue, and in that case the charm of making alterations vanishes, and what was once ardently considered to be an improvement turns out a mistake. That is not a mere possibility which may occur, but an unpleasant fact which has occurred a hundred times, as many gardeners know to their cost. A long experience has brought many instances of this nature under my notice. The last was the case of an earnest able gardener and a kind employer. The lawn was large, and by dint of hard work was well kept. It was surrounded by belts of trees, with shrubs and evergreens sweeping the grass. It also contained many large clumps of trees, &c., which similarly covered the ground, forming agreeable natural thickets and revealing little or nothing of the gardener's art. With these the master was satisfied, but not so the man, who, in spite of pleasantly-given warnings of the consequences of making more work, laboured hard and long in opening out the clumps, pruning the shrubs, raking the ground, and planting flowers. The neatness and trimness which he produced were at the first pleasing in his sight, but the labour of keeping the grounds in order exceeded his anticipations, and the garden as a whole could not be so well kept as formerly, and after working for a few years through “all the hours of daylight,” he was obliged to relinquish a charge which for

more than thirty years had afforded a comfortable home for his predecessor. A radical alteration had been made without sanction and encouragement, and what at first was pleasant to the eye eventually resulted in bitterness and disappointment to all concerned.

Other alterations which are really fundamental in the estimation of an owner may appear trivial in the eyes of a gardener, and a man should always consider well, and also make inquiries, before uprooting a tree, shrub, or plant which cannot be replaced. It is well to remember that there are plants and trees in many gardens which possess no real beauty, yet which are highly prized for the history which attaches to them, and of which a "new man" may be ignorant. Never shall I forget a mistake which I once made in destroying a common Rose bush. It had no beauty, for it seldom flowered, and it occupied space which I conceived might be rendered more attractive. A hundred pounds would not have purchased that Rose, for I found out when too late that it had been planted there after having been rooted from a cutting in a bottle of water by a dearly-loved son of my employer. That Rose was a memorial of the dead, and its loss was mourned more than would have been the loss of a jewel. I was forgiven for my thoughtlessness, but I have never forgiven myself. I have ever afterwards been careful never to destroy what may have been in my eyes unsightly without being sure that I was acting safely. A little inquiry costs nothing, and may save much. By acting on the principle of destroying nothing which has long been established on the property of another without a clear understanding from the owner, I have been enabled to pass pleasant years as a gardener, and am now rewarded by enjoying the confidence and respect of my previous employers.

The present is the time of changes, and new gardeners are going to old places. Let me ask them to remember two things—not to mar the character and reputation of their predecessor, nor hastily to uproot any old belongings of a place lest they should have a "hidden value" and a worth not to be estimated by their beauty.

This is also a period for "making alterations" generally. Let there be an understanding that these are not only required by the gardener, but also by the owner of the gardens, otherwise contentions may at some time arise, and the weakest will fall.

Because I wish to see disputes averted and confidence increased between employers and gardeners, and because I know that you, Messrs. Editors, desire the same, I submit this as the advice and experience of—A RETIRED GARDENER.

### MANETTIA MICANS.

"Stove evergreens—climbers." Such is the brief but comprehensive description applied generally to this genus in our "Johnson's Dictionary." It is somewhat vague, and if an approximate height were not appended to the description of each species, one would feel disposed to attribute the rarity of *Manettias* to a misconception of their real value by those who have only seen this description and have not had the privilege of beholding any of the plants in full flower.

Standing upon my desk close by me as I write is a plant of *Manettia micans*. It is November 22nd. A dull murky day of the true November type; a leaden sky, bare-limbed trees, decaying foliage meet the eye outside; but a glance at my plant robs the day of its dullness, for is it not bright with hundreds of gay flowers nestling among foliage of deepest freshest green? Let me describe the plant and its culture, and try if I cannot induce everyone having a plant house or pit that is kept at a winter temperature of about 55° to grow some of it. Including the pot my plant measures 2 feet high. It has a clear stem of 6 inches, being trained upon a wire trellis of the form of half a globe 10 inches in circumference, more for the sake of novelty than for any decided preference for that form, which in reality is not only concealed by the foliage, but is altogether lost sight of in the somewhat wild grace of the plant, for after the trellis was well clothed the growth was left to ramble unchecked by training of any kind, and so notwithstanding its wire supports it now presents very much of the free and graceful aspect of a wild child of Nature. The foliage, both in form and colour, closely resembles that of the *Bourvardias*, while the narrow tube-shaped flowers are bright scarlet tipped with yellow, each flower springing singly from the axil of a leaf, and as they have somewhat long footstalks, and are borne upon slender flexile branches, they present the most sprightly appearance imaginable. About a dozen plants

are now in full bloom. They are, moreover, growing freely, and abundant blossom buds are visible upon the young shoots, so that they will continue useful for a variety of decorative purposes for some time to come. Some of the plants are cone-shaped, others follow the outline of a balloon, but all are alike ornamental and useful.

Concerning the culture of these plants there is very little to say. The cuttings were taken in March, and they rooted freely in an ordinary hotbed. The young plants were potted in a free mixture of loam, old hotbed manure and sand; they were placed in a vinery, shifted into blooming pots 6 inches in diameter when they had plenty of roots, fastened to a trellis as the branches lengthened, syringed, watered, trained regularly, kept in the vinery till October, and then taken to the stove where they have in due course burst in flower. What can be more simple than such a cultural process as this? Certainly nothing can be more satisfactory than the present condition of the plants to which it has been applied.

I ought not to omit pointing out the value of this *Manettia* as a source from whence an abundant supply of sprays may be had to mingle with other cut flowers. The plants, too, may also be turned to account for clothing the pillars of a warm conservatory, and also for furnishing hanging baskets, either alone or mingled with other plants, especially with Ferns and Lycopods.—EDWARD LUCKHURST.

### THE RANUNCULUS.

It is with feelings of great regret that I have heard from Mr. Carey Tyso of Wallingford that he is obliged to give up, owing to ill health, the cultivation of this lovely flower, with which his name has been for so many years associated. He has been the chief grower of *Ranunculuses* in the south for a long time; and although of late one has missed his stands of beautiful flowers from our leading shows, yet there was a time when he was constantly taking prizes there and surprising the public with the symmetry and marking of his flowers; and thus the small band of florists in the south is lessened, and I suppose my own collection will ere long be the only one of any extent where these flowers are kept under name. In the hope, then, that some lover of flowers will make use of the opportunity—for Mr. Tyso is offering his roots at a very cheap rate; sorts which I recollect being priced at 10s. and 20s. a-piece now being as low as 6d.—of commencing their growth, I venture to put forth a plea for them.

I know of nothing more beautiful and refined in the whole range of florists' flowers than a bed of well-grown *Ranunculuses*. Nowhere is there greater perfection of flower, symmetry of shape, or variety of colour. Unlike the Carnation, *Picotees*, and *Pink*, they require no art of the dresser, for to attempt it would be like painting the Lily. Unlike the *Dahlia* they are dwarf in habit, but like it in the immense variety of colour. Amongst them you have olive, red, crimson, grey, white, purple, and almost black selfs. You have cream-coloured, yellow; grounds mottled, regularly spotted, and edged like *Picotees*; again white grounds spotted and edged, and others striped like a Carnation; and I think it is impossible to look upon a bed of well-grown and well-bloomed *Ranunculuses* without feelings of deep admiration.

But the question may be asked, Are they not very troublesome to grow? Yes, but is there any florists' flower that is not? And this I believe to be the secret of their decline, as it has been of *Heaths* and other plants we used to see so fine in former days. The great idea in modern gardening, at least in the minds of owners of gardens, is decoration. The conservatory must be "gay;" the garden must be a blaze of colour; and all the energies of the gardener are so taxed for this end that, except in very rare instances, can he (even if he have the inclination) carry on the cultivation of plants requiring so much care and making so little display. But to the amateur who cultivates his own little plot I would commend the *Ranunculus*: it requires care, but it will amply repay him for it.

The soil it delights in is a cool, close, not stodgy soil; but the finest beds I ever saw were grown in the ordinary soil of a garden. My present plan is to grow them in the beds in which I have grown *Gladioluses* and which have been well manured for them. This is sufficiently rich without adding any fresh manure, which the *Ranunculus* dislikes very much. There are two points in its culture on which great stress must be laid—the depth at which the tubers are planted, and the time of taking them up after flowering. I know not what is the reason,

but if the tubers are planted at any other depth than  $1\frac{1}{2}$  inch they do not seem to succeed; and hence I have aboard notched to that depth, and make the rows with it, so as to keep the crowns at the required depth. Then, again, they must not be left too long, especially in wet weather, after they have bloomed before the roots are taken up, for they very soon begin to start; and if they do, that is certain death to the tubers: hence it is best to put a covering over the bed to keep it from rain. I this year adopted the plan of placing the awning which I use for my two best *Gladiolus* beds over them; this not only kept them from rain when in bloom, but made the taking-up a much easier and pleasanter process.

I have little to say as to choice of soils. My own collection numbers 320 varieties, but, as in most florists' flowers, there are many so nearly alike that only the eye of a connoisseur can detect the difference. But should anyone be moved to undertake their culture they could not do better than place themselves in the hands of Mr. Tyso, tell him the limits to which they will go, and I will vouch for it they will not be dissatisfied with his method of treating them; and I should be glad to find that I have induced anyone to undertake the culture of a flower which is associated with my earliest garden love, and of the intrinsic merits of which I think so highly.—D., Deal.

#### DECIDUOUS TREES AND SHRUBS.—No. 4.

**LARCH** (*Larix europæa*) is perhaps the most generally useful of timber trees, and is also ornamental; but, as generally planted closely with other trees, the beauty of the Larch is not apparent. There is no objection to grouping the trees in masses, planting Scotch Firs, Austrian and Corsican Pines on the higher ground, and the Larch and Spruce separating the masses; and where commanding positions do not exist for the Pines, much may be done by grouping the subjects rather than disposing the trees equally over the whole surface. By one mode we obtain distinctness of view with variety, and with the other indistinctness—monotony. Similar remarks apply to a mixed hardwood plantation of Oak, Ash, Elm, Sycamore, &c. If taste be essential in every industry, in none is it of more importance than arboriculture.

In ornamental planting Larch has been singularly neglected. Only in a few instances are perfect specimens to be seen, yet what finer object can be in spring than a Larch 90 or more feet in height towering upward in graceful conical form, its branches starting at right angles from the stem, then gradually curving downward, anon near the extremity curving upward, from which emanate the graceful drooping spray clothed with soft green leaves and studded with its many incipient crimson cones? In autumn its foliage assumes a yellow, often an amber, tint, and is effective in association with the "frosted" foliage of Piceas and the darker hues of Pinuses. Plant Larch; it is the best of nurses for other trees, and is adapted for ornamental purposes. There are ample materials for a group, for besides the common Larch are the Red American (*L. americana*, syn. *microcarpa*); the singular Sikkim (*L. Griffithiana*); the bushy Dahurian (*L. dahurica*); and the Golden (*Pseudo-Larix*), the foliage of which in spring is light green, changing in autumn to a beautiful golden-yellow.

The Deciduous Cypress (*Taxodium distichum*), is a very handsome pyramidal tree, with foliage of exquisite loveliness from its fineness and autumn tints. This tree does not succeed in an exposed situation, preferring a free open soil and moist, but free from stagnant water. *T. sinense* is very elegant, its shoots having a feathery appearance, drooping in a graceful manner.

Deciduous trees with umbrageous heads are best as standards with clear stems of not less than 6 feet, nor exceeding 10 feet, and having finely-formed heads. Trees of this description tell well in parks either in groups or singly. Some of the most desirable are Maples, particularly the Norway Maple (*Acer platanoides*), which is of rapid growth, and has fine bold foliage. 50 feet. The Scarlet Maple (*A. rubrum*) having finely tinted leaves in spring and richer tints in autumn, 40 feet; it is a little less free in growth than the former. The North American ally, Virginian Red Maple (*A. virginicum rubrum*), though of less growth is more handsome (20 to 30 feet), and appears to need moderate shelter. Sycamore (*A. pseudo-platanus*) is good in a bleak situation, being of rapid growth and making a handsome head of bold foliage, and endures the sea breezes well. 50 feet. Its variegated form

is not so free in growth, and yet grows fairly in an exposed situation. It is very fine, its foliage contrasting well with the Purple-leaved Sycamore (*A. pseudo-platanus purpureum*). Both 40 feet. They will succeed in almost any soil, and make a fine group.

**HORSE CHESTNUT**.—Grand for avenues and noble for parks. In an exposed situation the trees do not do well, not even the common (*Æsculus Hippocastanum*), otherwise they are very free in growth and beautiful, alike from their flowers and foliage. 40 feet. A double white and double red (30 feet) do not grow so strongly as the species, and of lesser growth still is the scarlet (*Æsculus rubicunda*). 20 feet. These, with the variegated (*Æsculus Hippocastanum foliis variegatis*) form a very effective mass. In any soil freed of water they thrive, but flourish best in medium-textured loam overlying gravel.

**LIMES** do not succeed in high exposed situations, growing very slowly; but the better forms of the species (*Tilia europæa*)—viz., red-twigged (*T. europæa sanguinea*), and yellow-twigged (*T. europæa aurea*) must supersede the common kind. 60 feet. Limes are fine subjects for avenues and park scenery. The red-twigged variety is the best.

**ELM**.—Desirable alike for avenues and park scenery, and one of the very few trees that thrive amid the smoke of towns, adapting itself also to a variety of soils. English Elm (*Ulmus campestris*) does fairly in a high and exposed situation; Wych Elm (*U. montana*) has dense foliage and a fine tufted appearance. Of the English varieties the upright growth of the Exeter Elm (*U. campestris fastigiata*, syn. *stricta*), and the Purple-leaved (*U. campestris purpurea*) are very fine, and associated with the variegated Elm form a splendid group. All 80 feet, except the Purple-leaved and variegated, which are 40 feet.

**ASH**.—The tints of the Ash (*Fraxinus excelsior*) in autumn contrast favourably with the deeper tints of Oaks. The Ash is not in favour with planters, and less so with agriculturists. Nevertheless, it is one of the most valuable of timber trees, and from an ornamental point of view is not undesirable, though its late leafage and early fall of the foliage tell against it. 80 feet. *F. aucubifolia*, with finely variegated leaves, is effective. 30 to 40 feet. And the Walnut-leaved (*F. juglandifolia*) of North America is worthy a place. 40 feet. The Ashes do not thrive in high exposed situations, but require a good soil and a moist situation. *Ornus europæus*, or Flowering Ash, is a fine free-flowering tree, desirable for ornamental planting to a limited extent. 30 to 40 feet.

**BEECH**.—Noblest of landscape trees, succeeding in a bleak high exposure. It prospers near the coast, and on dry sandy or chalky soils, or moorland, water not being stagnant. The delicate tint of the tender leaves of the common Beech (*Fagus sylvatica*) light up the landscape in early summer, and afford a good contrast with the Purple-leaved Beech (*F. sylvatica purpurea*), the latter being particularly fine for scenic effect. There are varieties of both the common and Purple Beech with upright branches and twigs, and others of a more or less pendulous character. The latter form is much the best, being of a deeper purple in the leaves. Common Beech attains to a height of 70 feet, and the Purple to 40 to 60 feet. The Crested or Curled-leaved Beech (*F. sylvatica cristata*) is curious, being dwarf and dense in growth, 15 feet; Fern-leaved (*F. sylvatica asplenifolia*) grows but slowly, attaining to about 30 feet; and the Cut-leaved (*F. sylvatica incisa*) is pretty. 15 feet. These form an effective group.

**OAK** requires deep and good soil. The English Oak (*Quercus pedunculata*) is a noble tree for parks. 60 feet. It and the Turkey Oak (*Q. cerris*), 50 feet, in association with the Variegated Turkey (*Q. cerris variegata*), 30 feet, and Scarlet Oak (*Q. coccinea*), 50 feet, the leaves of which die off coppery scarlet, produce a fine effect. Marsh Oak (*Q. palustris*) does well on moist ground, having for an Oak a light, even elegant appearance. Its leaves in autumn pass through various tints, dying off orange-red. The Golden Oak (*Q. pedunculata concoloria*) has bold foliage of a golden hue, and is effective in contrast with the dark, glossy, green foliage of *Q. pannonica*.

**ACACIA**.—This is much neglected, for being of quick growth, having a very elegant appearance, and being a fine-flowering tree is much more desirable for avenues than denser-foliaged trees. Acacias succeed fairly in the environs of towns, and succeed in most soils. The light green of the foliage is maintained throughout the summer. Besson's Acacia (*Robinia Bessoniana*) is very noble and quick-growing; Decaisne's (*R. pseudo-acacia Decaisneana*) is also a vigorous grower with rose-coloured flowers; the common Acacia (*R. pseudo-acacia*) is not so much

seen as it deserves. *R. pyramidalis* grows upright, and is highly ornamental.

**BIRCH.**—An attractive tree, thriving well in wet ground, even bogs, and is particularly fine near water. The White Birch (*Betula alba*) associates well with Pines in wet moorland, and is fine everywhere. The Fern-leaved Weeping Birch (*B. alba incisa pendula*) is very ornamental.

**ALDERS** are suitable for skirting rivulets, doing well in wet swampy ground, and are appropriate for association with water. The common Alder (*Alnus glutinosa*), the Cut-leaved (*A. glutinosa laciniata*), and Hoary-leaved (*A. incana*) are the most desirable.

**POPLARS** are subjects of the valleys, preferring open moist soil. Though they do not survive long in towns, their rapid growth renders them desirable. I have seen the Lombardy Poplar thriving in a smoky atmosphere where the Black Italian (70 feet), Balsam (70 feet), and Ontario (70 feet) had succumbed. Lombardy (*Populus dilatata* or *fastigiata*), 70 feet, from its erect spire-like habit is valuable for forming a screen where spreading trees would be objectionable. The Silver-leaved (*P. alba nivea*), 40 feet, is particularly fine, its clear silvery-coloured foliage having a distinct effect.

**WILLOWS** do well on poor wet land, and grow rapidly; but except in their weeping form their beauty is not striking. In winter, however, the wood of some of them when seen in a mass is ornamental, particularly the scarlet, purple, and yellow-wooded. *Salix Solomoni* is a hardy form of the Babylonian Willow; it, Kilmarnock, and the American Weeping Willow are effective on islands, or otherwise associated with water.

**SPANISH CHESTNUT** (*Castanea vesca*) requires strong soil and a flat country, not succeeding in high ground unless sheltered. For parks it is a noble bold-foliaged tree. 50 feet.

**PLANE.**—Like the Spanish Chestnut Planes do not succeed in high exposed situations, but will thrive in most soils, climate being favourable. The Western Plane (*Platanus occidentalis*) is a fine tree of free growth, with ample pleasing green foliage, having a very ornamental appearance, and succeeds in towns better than any other tree. 70 feet. The Oriental Plane (*P. orientalis*) is not nearly so free in growth as the Western Plane, but is nevertheless good in any but exposed situations. 50 feet.

**WALNUT.**—Requires good soil. It does not succeed in high and exposed situations, and is not particularly desirable as a landscape tree. The Cut-leaved Walnut (*Juglans regia laciniata*) has very ornamental foliage. 20 feet.

I have thus noticed some of the most desirable of useful and ornamental trees which are suitable for parks and rural scenery generally, and for association with them are smaller trees mostly ornamental for their flowers or fruit. Some of the most desirable are Thorns, which succeed admirably in and around large towns. Some have very beautiful flowers filling the air with fragrance, and others have not only fine blossom but highly coloured berries (haws). The finest of all for flowers are Paul's Double Scarlet, Double Pink, and Double White respectively; *Crataegus oxyacantha coccinea plena*, *C. oxyacantha rosea plena*, and *C. oxyacantha plena*. *C. fructuflavo* has yellow berries; *C. grandiflora*, large flowers like a *Mespilus*; *C. coccinea*, fine large fruit. *C. coccinea corallina* is even finer. *C. glandulosa purpurea* has reddish foliage. *C. cordata splendens* has very bright shining leaves. *C. Leeana* is a fine variety of the Tansy-leaved Thorn (*C. tanacetifolia*). The finest of the genus is probably *C. stricta*, which grows erect, and is therefore valuable as a screen in town gardens, and for decorative effect in churchyards and cemeteries. All 15 to 20 feet.

**SNOWY MESPIUS** (*Amelanchier Botryapium*) in early spring is very effective from its abundant white flowers, but does not succeed in exposed situations. 15 feet.

**CHERRY.**—The common Cherry (*Cerasus avium*) is fine in spring from its many fair white blossoms; but the Double-blossomed (*C. avium multiplex*) with its large pure white blossoms is much superior. 15 to 20 feet. Few trees are more ornamental in spring than the Bird Cherry (*Cerasus Padus*). A tree of this with a round head 30 feet through its branches and 20 feet high is no despicable object. The Cornish Bird Cherry (*C. Padus rubra*), with the Aucuba-leaved variety (*C. Padus aucubæfolia*), are effective. They do well in most soils. 20 to 30 feet.

**ALMONDS** like a sandy or well-drained soil. They blossom freely, and are the first to gladden us in spring with their fine rosy flowers. The common Almond (*Amygdalus communis*) or fruit-bearing, and the double-flowered (*A. communis flore-pleno*) are good. 15 feet.

**LABURNUM.**—The Scotch Laburnum (*Cytisus alpinus*) is much the best, its long racemes of bright yellow flowers being very effective. 30 feet. Common (*Cytisus Laburnum*) is smaller in every way. The purple-flowered (*C. Laburnum purpureus*) from its colour, and *C. Laburnum autumnalis* by its season of flowering, are desirable. 20 feet. Common as Laburnums are, they deserve a place near every dwelling. The trees do well near smoky towns.

**PRUUS.**—Mountain Ash (*Pyrus aucuparia*) succeeds in high and exposed situations; its elegant foliage and bunches of red berries being effective in the autumn. 30 feet. The White Beam (*P. Aria*) is no despicable object, but is surpassed by its variety *P. Aria corymbiflora*; and the wild Service Tree (*P. torminalis*) does well in hilly or mountain districts.

Apple and Pear trees do little good in smoky town gardens, but I have not seen anything finer in the way of blossom than those are, whilst the fruit of Crabs is very effective in the landscape in autumn. What finer in autumn than the highly coloured, crimson, small shining fruit of the Fairy Apple, or the larger fruit and as highly coloured of the Imperial Crab? both varieties of the common Crab (*Pyrus Malus*). The Siberian Crab (*P. prunifolia*) is truly a lovely object in spring with its pink blossoms, and highly ornamental in autumn when loaded with its small highly coloured fruit. The red-flowering Crab (*P. floribunda*) yields to no other in its season, which with the Chinese (*P. spectabilis*), vars. *flore-pleno*, *Kaido*, *Imperialis*, and *rosea flore-pleno* have quite a charming effect from the profusion of their beautiful blossoms. The Pears, especially the double-flowered (*Pyrus communis flore-pleno*), *Bollwylleriana*, and *præcox*, are fine in spring and ought to have a place in ornamental planting.

**JUDAS TREE** (*Cercis Siliquastrum*) is attractive by its purple flowers. There is also a white variety. I regret to add they do not succeed except in sheltered situations.

**COTONEASTER FRIGIDA** does well in a moderately sheltered situation on high ground, and its bright scarlet berries are very handsome in autumn. 20 feet.

**KOLREUTERIA PANICULATA** is very ornamental alike by its leaves, mode of growth, and long spikes of yellow flowers. 20 feet. Unfortunately it only succeeds in sheltered situations and well-drained soils.

**TULIP TREE** (*Liriodendron tulipifera*) is a large tree with dense Plane-like foliage, and yellow and red Magnolia-like flowers in June. It does not attain to large dimensions unless in favourably sheltered situations, where it occasionally attains to a height of 60 feet.

**MAGNOLIA ACUMINATA** has a fine effect from its candelabra-like habit, bold open foliage, and yellow and green flowers. It requires moderate shelter, and with that does well in high well-drained ground. I have seen a tree of this some 45 feet in height on the Welsh mountains. *M. glauca* is much more dwarf, and does well in wet ground of a peaty character, but requires shelter. 15 to 20 feet. Of *M. glauca* there is a white-flowered variety—viz., *M. glauca Thomsoniana*, the flowers being fragrant. It also needs a sheltered situation and peaty soil.

**SALISBURIA ADIANTIFOLIA** is very distinct in foliage and pleasing, but is unfortunately of slow growth, except in well-drained soils in sheltered situations. 20 feet.

**MULBERRY.**—This has a distinct appearance, but its period of leafage is short. The White Mulberry (*Morus alba*) is the freest grower. 30 feet. But the Black (*M. nigra*) is the most desirable. 20 feet.

**PRUNUS MYROBALANA** (the Cherry Plum) has large white flowers in early spring, having a very effective appearance. 20 feet. The double Sloe (*Prunus spinosa flore-pleno*) is a mass of white in early spring; quite charming. 10 feet.

I will close my list with the very distinct and elegant Stag's-horn Sumach (*Rhus typhina*), very ornamental from its erect dark-coloured flower heads and conspicuous foliage, especially in autumn, when the leaves before dropping change to a very beautiful purplish-red.—G. ABBEY.

## DIOSPYROS KAKI.

Your correspondent, "G. S.," asks some questions about our fruit of *Diospyros Kaki*. A friend who knew the *Diospyros* in Japan assured me that the fruit was excellent. I was therefore much disappointed at the unpalatableness of our specimens; I believe that there are many varieties in Japan. If our first cultivated Apple tasted as a dessert fruit had been Yorkshire Greening or Norfolk Bessing we should have

wondered at accounts of flavour which had, perhaps, come from the eaters of Cox's Orange or Ribston Pippin. The Kaki fruit I first tasted was quite ripe, and I feel satisfied at its best stage; one side was beginning to decay, but all the rest perfectly sound. I will with pleasure try my last fruit at its extreme point of ripeness, though I think this was done in the specimen above spoken of. We have another tree which has not yet fruited, apparently another variety.—GEORGE F. WILSON.

[There are more than fifty species of *Diospyros* known. We have tasted several in India, but all were bletted like the Medlar when fit for eating. One species is hardy, *D. virginiana*, called popularly in North America the Persimmon, and its fruit is not palatable until it has been frozen.—EDS.]

### ORCHIDS AT CHELSEA.

THE recent large importations have brought down the price of some Orchids very considerably, and I was told by the Messrs. Veitch that the demand for them was never so great as it has been this year. When people are purchasing imported Orchids they ought not to drive a hard bargain, for in thinking of them one is vividly reminded of the cry of the Newhaven fishwife trudging through the streets of "Auld Reekie," shouting "Its no fish yer buyin, its honest men's lives." Witness the long array of martyrs who have perished in their search for the rare and beautiful in nature, from David Douglas goaded to death by a wild bull, to Albert Bruchmüller brutally murdered by a convict in New Grenada.

The splendid *Odontoglossum cirrosum* is to be seen at Chelsea in thousands. It is not new to England, having been introduced in 1840 from Ecuador, where it was found at an elevation of 6000 feet above the sea; but, like many other fine plants, it was lost owing to ignorance of its treatment. It is best described as a major form of the rare and beautiful *O. niveum majus*. The spikes are large and branched, and I can testify to the free growth of the plants in a cool house. Another surprise to me was to see suspended from the roof in baskets and on blocks hundreds of the magnificent *Oncidium Rogersii*. The collector, who has had much experience, has no doubt of its being the real thing. Should it not prove true, it will doubtless be a new *Oncid* of great excellence.

Masdevallias now almost require a house to themselves, so numerous are the different species and varieties, some of them more curious than beautiful, but all are worthy of culture. Were I to choose three species only, I would take as the best *M. Harryana*. The best variety is a magnificent flower, dazzling glowing crimson in colour. Next, *M. Veitchiana*. The best variety has thick fleshy leaves and flowers, and the colours are most striking. Lastly, the pure white *M. Tovarensis*. By the time this appears in print Messrs. Veitch will have in flower perhaps the finest plant of this species in England.—J. DOUGLAS.

### AMERICAN BLACKBERRIES.

THE Lawton is perhaps the best of the American Blackberries; the fruit is delicious, having very small seeds in proportion to its size; and the cultivation of this fruit is so easy that no person need fail of a crop. The plants flourish in any strong moderately-rich soil with good under-drainage. The common, and with many the easiest, way is to plant in rows 6 feet apart, the plants being 3 feet apart in the rows, driving a stake 5 feet high to each plant or stool to which the young canes are tied. But having grown these Blackberries I can name a better plan: Procure sound oak posts and fix them in the ground, the height of them being just 4 feet from the surface of the soil, and have them well braced and firmly planted. Set one at each end of the rows of plants, and from one to the other of these posts strain a strong wire, supported at intervals of about 40 feet with stakes driven into the soil, to which the wire is to be pinned with small staples. These posts should not be set exactly in the line of the plants, but 18 inches or 2 feet on one side, so that the canes may be bent over to the wire; thus allowing the young canes of this season to come up separate from the bearing canes, which facilitates the picking. In the end this trellis is not more costly than staking, and is far neater and lasts as long as the plants, which will yield good crops of fruit for six or eight years. There are other sorts, such as the Kittatinny, Wilson's Early, Wance's Seedling, Western Triumph, &c., but the best, in my opinion, is the Lawton.

The way to establish a healthy stock is to layer the canes in

August or September as follows:—As soon as the tips grow nearly bare of leaves and present a dark purple colour peg them into the ground 3 or 4 inches at an angle of 45°. In a few weeks they will form fine matted roots, and can be transplanted after cutting off from the parent 4 or 6 inches above the root. If very strong plants are wanted, and quality or size more than quantity, check the new growth when 2 feet high, it will then throw out ten to a dozen side branches, and these being layered early form very large matted roots by the autumn. But if a large increase of plants is desired check the growth of all these side branches when they are about 2 feet in length; this will cause each branch to shoot out, and instead of having ten or a dozen to layer, fifty to one hundred will be produced around a good-sized bush. The plants from these will be much later, and besides do not grow such strong canes; but my experience has satisfied me that these smaller plants are the safest to plant, especially in large quantities.—H. S. J.

### WRIGHT'S SELF-ADJUSTING STEP LADDER.

At St. Louis the other day we examined different sizes of Wright's self-adjusting step ladder. Mr. Wright is a practical fruit-grower, noted in St. Louis and Missouri for his Wright's Mammoth Peach as well as for the step ladder, which is a result of his experience in the Peach orchard, and therefore worthy of special attention by the fruit-grower, although

Fig. 69.—Wright's Self-adjusting Step Ladder.

equally useful for the ordinary household purposes of a step ladder.

The peculiarity of this ladder is that the bracing legs of it are each hung on a kind of universal joint instead of the ordinary hinge, and connected by a triangular brace also hung from the upper step by a similar joint, the result of which is that the braces adapt themselves to uneven ground and leave the step-ladder part in a firm upright position, provided that part only is on level ground. Provision is made for elevating either side of this also where the ground is unusually uneven.—(*Rural New Yorker*.)

### THE CULTURE OF THE POTATO.

I HAVE been watching the growth of this vegetable for some time past, and I do not think that we plant it early enough. The self-set Potato, as it is commonly called, usually produces more Potatoes than those we plant. For instance, in the past hot and dry season the Potatoes which were planted late in the spring were in the months of June and July quite at a stand still when they ought to have been making the best of their growth; and then at the latter end of September and the beginning of October, when they ought to have been ready for taking out of the ground and storing, we found them in the full vigour of growth, and were left in the ground for another month or six weeks, in order to make up a good crop, ending in too many cases only in a crop of disease. It is my opinion that if the Potato was planted in the month of January on

well-manured ground that we should have better crops, and that we should not be troubled nearly so much with the disease as at present. The sets should be planted 6 inches in depth. By planting thus early some may fear that the tops would be cut down by the frost in spring, but self-set Potatoes are seldom cut down with frost, and that is why I advocate early planting.

Potatoes are often spoiled in storing them away. If the tubers are thrown together when they are damp into a very large heap it is quite certain that they will heat, and the steam cannot escape through the thick covering of soil which is placed over the heap, and hence many of them rot. My opinion is that Potatoes should be stored dry and cool, and in such a manner that any steam can escape from them, and the bulk of them will then remain sound and good.—A YOUNG AMATEUR.

### MANURING AND PLANTING ROSES.

I THINK Mr. C. H. Kitching is right in his idea of manuring Roses; but my opinion is that leaving Roses on Briars in the ground five or six years is a mistake. Not everyone who grows Roses has the time to spare to take them up every year, but every two years they should be taken up and root-pruned; and Roses properly treated in this way will never fail to flourish. The first week in November is the best time for removing them; a good soaking of liquid manure twice a-week in hot weather is very beneficial.—E. BROOK, *Westbere, Canterbury.*

### MR. CHARLES VAN GEERT'S NURSERY AT CALMPHOUT.

BELGIAN nurseries have been frequently referred to, but these have mostly been the "manufactories" of plants more or less of a tender nature, and which are in general demand for indoor decoration. Such plants as Palms, Ferns, Aroids, Gloxinias, Camellias, Azaleas, &c., are increased and grown by hundreds of thousands in nearly all the nurseries of note in that small but thrifty kingdom. Most of the nurseries, therefore, are much the same in their general features, and vary only in extent, details, and a few specialities with which one or the other of them is identified. The nursery now to be noticed is, however, totally different from the establishments which are so common in Belgium, and it is also somewhat out of the beaten track of the ordinary wandering horticulturist. It is a nursery of hardy plants and trees, and especially of Coniferae. A pure air being therefore essential, the site was chosen some distance from the smoke of towns, and where the soil was also found favourable for this class of ornamental trees. The present being the period not only when evergreens and Conifers are seen in their best garb, but also the time for removing and planting them, Mr. Van Geert's collection may appropriately be noticed.

The proprietor of the Calmpthout Nurseries has a "home nursery" attached to his residence in the Rue de la Provence, Antwerp. It is here where tender plants are raised and grown in several glass structures, also where the seeds of Conifers are sown, and where the seedlings are tended and established. It is here, too, where the choicest of the rich collection of hardy trees with variegated foliage are increased, such as that valuable acquisition the Golden Poplar, *Populus canadensis aurea* Van Geerti, the finest of all golden-foliage hardy trees, of free and noble growth; and not golden in Belgium only, for this tree has proved in the Hammersmith nurseries of Messrs. J. & C. Lee all that it was represented by its raiser, as being as free in growth as the common Canadian Poplar, and with leaves not of a sickly hue, but of a warm and vigorous golden tint, the colour increasing in intensity the better the trees are nourished and the more they are exposed to the sun. Easy as this tree is of increase, the great demand for it has taxed to the utmost Mr. Van Geert's endeavours to establish a sufficient stock, and consequently the trees in the Antwerp nursery were all in a small state. This tree, which in all probability will in a few years lighten and brighten the park and forest scenery of many countries, is the result simply of attentive observation and the turning to account, as it were, a freak of Nature. Mr. Van Geert in passing through a much-frequented district had noticed a bright yellow branch growing on an ordinary Poplar tree, and observing that it grew as freely as the rest part of the tree, that it assumed its golden tint early in the summer and preserved it throughout the season, that this was not a freak peculiar to one season but was the same year after year, the tree or branch was secured for further experiment, and thus the tree which will add so

much to landscape scenery and its preserver's fame was obtained, increased, and distributed. Thousands of passers-by had noticed the "golden patch," but one only had turned the circumstance to account—the observant and fortunate Charles Van Geert.

From Antwerp to Calmpthout is about an hour's ride by rail. The station is contiguous to the "home nursery," and tickets are quickly procured. On the Belgian railways the fare is printed on every ticket, and the second-class rates are somewhat less than the ordinary third-class charges in England. The speed of the trains is not so great as in England, but the carriages are equally well fitted, and travelling if not fast is comfortable. There is also a striking difference in the general demeanour of travellers in the two countries. The Belgians are very much "Frenchified" both in language, and deportment—politeness. Each appears anxious to be on the pleasantest of terms with his neighbour; and "bows and smiles," which appear common to all, are freely interchanged. Conversation is conducted—I had almost said "fiercely," but I must politely modify the term into animated—in proportion as the speakers have left the old Dutch or Flemish school and are merging from "mynheers" to "meesters." It did not appear to be "quite the thing" to "skulk behind a newspaper," or to trample on as many corns as possible in rushing in or out of a compartment. Politeness is cheap, but "John Bull" has not time to raise his hat sixty times a minute; but as he is generally regarded as having a pocketful of francs his brusqueness is excused, and he receives the best of attention in Belgium. That is, of course, when as a stranger he is dealing with strangers; but as friend meeting friend none than the Belgians can be more kind, more hospitable.

On leaving Antwerp the train appears to be kept as long as possible within the fortifications—that is, the course of the line is somewhat tortuous, and it is not until after traversing some two miles that we penetrate the frowning earthworks by a tunnel bearing the national arms, and emerge in the open country—open but not unprotected, for its depression and flatness is such that the waters of the Scheldt can be let loose and the district be submerged, so that an invading army would have to literally pass through sea and fire before entering the precincts of the "strongest fortified city in Europe." The district around Antwerp is proverbial for the fertility of its soil, and the inhabitants are regarded as being especially thrifty and industrious. Their thrift I will not question, but their industry has probably been overrated. Men and women alike work in the fields and gardens, the women seeming to enjoy it the most, but the Belgians do not "go in" with the zest and vigour of honest English labourers. I say "honest" because all are not entitled to that honourable designation, for in too many instances honesty has degenerated into shiftiness, and whenever that is the case the man will lose more in the end than will the master.

The land nearest to the city is devoted to the cultivation of vegetables, but I much doubt if the market gardens of Antwerp are so productive as the market gardens of London. The evidence afforded by the steamers is in favour of the London gardens, for, besides supplying the enormous demands of the metropolis, large shipments of vegetables are sent over to Antwerp, especially, I believe, of Rhubarb and Celery, which crops would thrive luxuriously in the cool, rich, alluvial soil of Belgium. Further from the city the land is devoted more to agriculture. The plots of the respective holders appear to be small, and the majority of them pay their rent in kind, not in money. The landlord finds the land, the tenant finding seed, labour, and manure, the crops being equally divided. In other parts of the kingdom the peasants are small proprietors, but a poverty-stricken look pervades many of the miniature plots and their owners. These humble "statemen" may be as contented as English labourers, but they certainly do not look so well, and do not enjoy such substantial sustenance and comfortable homes.

Still further in the country we come to higher and more sterile soil, a sort of grey sand, in which scarcely anything will thrive except Scotch Firs (*Pinus sylvestris*). Plantations of these Pines are established, not by planting the trees but by sowing their seeds. The growth of trees which have not been removed is much cleaner and quicker than that of transplanted trees. The ground is levelled and set out in beds of about 10 yards wide. On these beds the Fir seeds are sown broadcast and thinly. From between the beds the soil is dug and thrown over the seeds, the ground when finished being formed into a series of ridges and trenches. In this way the trees

grow freely, which by transplanting would assume a stunted appearance and be of little value. They are thinned-out as they advance in growth, and are devoted to many useful purposes according to their size, and the plantations become profitable. Beyond what may be termed this sterile belt is Calmthout, and we alight at a small country railway station close to the nursery. Just within the gates is a large white house (all the Belgian houses worthy of the name are white, a few of the peasants' dwellings being bright blue, green, orange, or some other gay colour indicative of the proprietor's rank, political creed, or fancy), and on the white house *Ampelopsis Veitchii* is very effective—a climbing plant worthy of carrying the honourable name of the great nursery firm into all lands.

The Calmthout Nursery is not large, perhaps ten acres, but its owner has so arranged it as to be ornamental as well as useful. The end next the public road is bounded by a fence of a somewhat novel kind. The lower portion of it, about 4 feet, is an Ivy hedge, the framework of the Ivy being ordinary wire netting supported by oak posts. It is thus an evergreen fence taking up little room, and is neat and durable. But the posts supporting the fence are carried up to a height of 9 or 10 feet; they are somewhat less than that distance apart, and cross pieces are placed from post to post, forming a series of arches. These posts and arches are covered with Ivy and with Virginian Creepers, and the nursery is viewed through these open frames of greenery. Parallel with this fence and at a distance of 5 or 6 yards is another fence, and along each fence have been planted tall trees of Weeping Beech. From post to post across this space wires have been stretched, forming a series of diamonds, and to these wires the branches were trained when in a young state. That was some years ago, and the branches of the trees now need no support; they grow in a perfectly horizontal position, and form a covering to a long and spacious living corridor which is at once novel in appearance, and is cool and grateful for promenade in the sultry days of summer.

This corridor forms the eastern boundary of the nursery, and from it are openings into the different divisions of the ground. These divisions are defined by very narrow and perfect hedges of Conifers which divide the ground into sections, the spaces between the hedges being about 12 yards wide, a narrow path leading down the centre of each section. At intervals of 50 yards or so are also cross hedges rising in altitude as they approach the path, forming a series of arches for passing under. In the centre of the nursery the arrangement is different. Here the space is wider than the side compartments, and it is mainly occupied by 250 squares formed with hedges 1 foot wide and 2 feet high of *Thuja occidentalis*, the front side of each square, however, being open to the central walk. These hedges were planted fifteen years ago, 10,000 *Thujas* having been employed in their formation. In the centre of each space was planted at the same time a choice Conifer, with the intention that it should remain permanently to form a perfect specimen. This idea has not been quite carried out. So urgent had been the desire for some of these that they were removed; a few others failed to flourish, while several of the specimens remained in their little compartments. At the back of each of these two rows of squares are rows of pyramid Purple Beeches and variegated Maples, alternately planted at a few yards apart. These are stately towering specimens, and have been skilfully trained, pruned and tended. Many of them are 18 feet in height and quite straight, the diameter of their branches near the ground not much exceeding 2 feet, each tree tapering upwards to a point; they are in fact perfect and regularly formed cones, and the deep colour of the Beeches with the alternating lightness of the Maples produce an effect that can be better imagined than described. The view down this, the main and central compartment of the nursery, is strikingly novel, and is perhaps in its way unequalled.

The principal divisional hedges referred are 7 to 8 feet high, and are kept in perfect order. There are, for instance, hedges of Spruce not more than a foot wide, Yew, Corsican Pines, Weymouth Pine, very distinct; *Abies canadensis*, Virginian Juniper, very close and elegant; *Arbor Vitæ*, and another extremely pleasing hedge of *Cupressus thyoides*, syn. *Chamaecyparis sphaeroidea*. Besides being ornamental these hedges are important as affording valuable shelter to the young stock of Conifers—the district being naturally bleak and exposed—and by the assistance which they render in this respect to the thousands of valuable plants far more than compensate for the little strips of ground which the hedges occupy. The narrow divisions are in other respects found to be advantageous

in enabling the stock to be seen to the best advantage, and, the divisions being numbered, the stock of any given Conifer can be found by anyone when directions are given as to the number of the compartment, and a saving of time is thus effected. It is very enjoyable to walk up and down these longitudinal divisions where collections of the various Conifers can be seen so conveniently, and the stock of these is not only extensive and varied, but is also choice. Throughout a long and successful career as a horticulturist Mr. Van Geert has made hardy ornamental trees his special study, and his business connections extend to all the nations of Europe.

A detailed enumeration of all that is noteworthy in this nursery is out of the question, yet the stock must not be passed entirely unnoticed. *Abies Menziesii* attracted attention. For this distinct and elegant Conifer Mr. Van Geert was awarded the gold medal at the Cologne Exhibition in the class for new and useful timber trees. It is hardy, elegant, and a most rapid grower. Its leaves are solitary, thickly placed, narrow-pointed, and incurved. They are silvery above and bright green below. This tree was found in California and the island of Sitcha, where it grows to the height of 80 to 100 feet, and its timber is very valuable. In anticipation of a demand arising for this promising Fir large stocks are being raised at home and abroad, and young trees are now procurable at moderate prices. Mr. Van Geert's stock of this Conifer was very vigorous. Noticeable also was a variegated form of *Taxus canadensis* which originated at this nursery; it is very attractive, and forms a handsome dwarf close pyramid. Another new and distinct Yew was *Taxus pendula aurea* Van Geerti, a drooping Golden Yew, which was being "worked" largely in anticipation of a brisk demand for "golden umbrellas." All the choicest of the *Retinosporas* were here in considerable numbers; also *Cryptomerias*, *Biotas*, *Thujas*, &c. *Pseudo-larix Kämpferi* is largely grown to meet the increasing demand; and very distinct was *Buxus Fortunei longifolia*, its foliage being of a distinct lively green, and distinct from all others of the family. Here is also the original plant of the Japanese *Taxus* (*T. cuspidata*) brought by Van Siebold, which is now an attractive specimen; and a striking example of *T. Koraiana* in the form of an inverted pyramid is worthy of mention. This elegant and hardy Conifer has leaves much longer than those of the Irish Yew; it is rather a slow grower, but it is very ornamental and worthy of a place in most gardens. *Abies nigra rubra* pumila formed a handsome globe of 6 feet in diameter, dense, and of perfect symmetry. Of *Abies orientalis* there was a noteworthy specimen, and also many others which must be passed over.

The collection of variegated and drooping deciduous trees is varied and extensive. Of striking appearance near the Weeping Purple Hazel was *Caragana pendula*, a Leguminose tree, and allied to the *Laburnum*. This is probably a drooping form of *Halimodendron argentea*, the Salt Tree. It was extremely effective, its leaves being of creamy whiteness, and its branches gracefully falling. A new hardy red Maple, *Acer Schwedleri*, had leaves as large as those of a Vine, very distinct; and *Acer polymorphum* was being prepared on its own roots, on which it endures the winter better than when grafted. In this nursery is the residue of the stock of standard Mistletoe trees which was referred to in this Journal some months ago. Only a few of these novel trees are left. Berries had been placed on Thorn stocks, and perfect round-headed Mistletoe trees were formed; a few sprays of the Thorn had been allowed to grow amongst the Mistletoe to encourage the growth of the latter. The Mistletoe heads were a foot to 18 inches in diameter, and had been laden with berries—the Thorn stocks being 4 feet high. As Christmas ornaments nothing than these remarkable miniature trees could be more effective, and the plan of raising similar "toys" is very worthy of being tried in this country.

Mr. Van Geert is adding to his nursery at Calmthout, and has recently planted a large piece of ground principally with shrubs and trees of drooping habit and having variegated foliage. The boundary of this portion next to the public road is fringed with a festoon of Clematises, and a corridor is being formed similar to the one above noticed. This second corridor is mentioned for the purpose of noticing the peculiar value of *Carpinus horizontalis* as a "roof" tree. This Hornbeam is remarkable for the horizontal growth of its branches, and only the slightest possible training is required to form a flat dense roof of foliage. This tree is a quick grower and hardy. Another fact is worthy of being recorded. In a pool in the nursery is growing the blue-flowered stove aquatic plant—

*Pontederia cordata*. It has been there for some years, and although it is killed down to the surface of the water every winter, it has never failed to grow again in the spring, and much more vigorously than it is usually seen in English stoves. This plant having proved thus hardy in Belgium ought also to be hardy in England.

An account of this interesting nursery would be incomplete without an allusion to Mr. Van Geert's mode of manufacturing manure and applying it to the soil. The manure manufactory is of a very homely character, and the process is extremely simple, yet very effectual. There is no digging of farmyard manure into the ground in the ordinary manner; first, because manure of that character is unsuited to this class of plants and trees; and secondly, some of it would be placed in the ground where not wanted. The plan adopted is first to obtain a supply of what is suited to the soil and crops, and then to apply it exactly where wanted and nowhere else. The manure, then, must have as its base vegetable matter, yet must be rich—that is, a minimum amount of the material must contain a maximum quantity of food. The manure is prepared somewhat as follows:—A shed is erected which contains bags of chemical manures, and beneath the shed is a tank or pond, in this the “artificial” are mixed at a tolerable strength. Into this liquid decayed and decaying vegetable matter of all kinds is placed and left for saturation. After remaining for a time it is taken out and placed in a heap, and fresh refuse is placed in the tank. Leaves, weeds, and rubbish have a soaking in this rich liquid. The saturated mass is subsequently turned over frequently, and in the course of time resembles leaf soil, and when in this state and sufficiently dry it is ready for use—an enriched, light, friable, vegetable compost. It is used as follows: The soil is light and sandy, and is not regularly dug over, but rows of holes are made of a sufficient size and depth for the different sized shrubs, &c. In these holes is placed a little of the compost—say a lining of an inch or two in each hole, and the planting is completed. It is to be remembered that this is a nursery, and the trees are subject to removal at any time, and masses of fibrous roots “close at home” are of the greatest importance, ensuring the safe and speedy re-establishment of the shrubs, &c. This compost and mode of applying it causes the emission of these masses of spongioles with the greatest certainty. I saw many Conifers taken up, hundreds being in the course of removal, and I never before saw such satisfactory roots. Shrubs so perfectly furnished with innumerable feeders could not fail to flourish if ordinary attention were bestowed in removal and planting.

The principle of applying the manure is a sound one. If the roots cannot find food near they will travel in search of it, and become long, straight, and comparatively destitute of fibres; but if nourishment of the right kind is provided numerous fibres are formed to appropriate it, and which remain in the feeding ground to the advantage of the subjects and their owner. It is so with plants of all kinds, from the Vine to the Cabbage, from the “Cedar of Lebanon to the Hyssop growing on the wall.” To his care in preparing this compost and applying it Mr. Van Geert attributes much of his success, for shrubs and Conifers so prepared have proved what are known as “certain growers,” and have established the reputation of the nursery. It is worthy of mention, and may in a modified form be advantageously adopted in the removal of trees and shrubs in private gardens, a little fresh generous compost to which is a great incentive to the emission of fresh roots. I apprehend it is in some such manner as above shadowed that the Belgian leaf soil is prepared in which Camellias, Azaleas, &c., root so freely and grow so luxuriantly. Certain it is that more attention is given to the preparation of light stimulating vegetable soil in Belgium than in England.

Mr. Van Geert's home nursery was described in vol. xxiii., page 429, and is much in the same state now as then; so is its owner—hale, courteous and hospitable, an excellent English scholar, and esteemed for his probity at home and abroad. He is ably assisted in his business by his son, Mr. Charles Van Geert, jun., who is a diligent and devoted horticulturist.—J. W.

## ASPECTS OF NATURE—NOVEMBER.

“Now the leaf  
Incessant rustles from the mournful grove;  
Oft startling such as, studious, walk below,  
And slowly circles through the waving air.”

THE above description is true of the first days of November, when there is, as it were, a stillness and repose about nature

which might almost cheat us into the belief that a long season of soothing rest was at hand; but sudden changes are frequent during November, and a day of pleasant sunshine is often followed by wet or frosty nights; or sudden tempests rise, till

“O'er the sky the leafy deluge streams,  
Till, choked and matted with the dreary shower,  
The forest-walks at every rising gale  
Roll wide the wither'd waste and whistle bleak.”

Thus the pale descending year has many aspects. Soft balmy days, seasons of high winds, driving rains, and frosty mornings alternate in so capricious a manner that it were impossible to assign characteristic weather to the variable month; nor lately has its customary description of “gloomy” been entirely deserved, for bursts of spring-like sunshine have lit up the landscape, and brought into conspicuous notice each plant and flower that still linger to deck the brow of the dying year.

On the common the Furze stands out in bold dark green masses, and under its sheltering cover smaller plants nestle and bring forth a few late blossoms. One of the most conspicuous features of the landscape at this season is the number of spiders' webs that are hung on almost every branch and leaf. The gossamer webs are woven between the pendant boughs of the Bramble and over the spine-covered Gorse; they twinkle in the early light with myriads of dewdrops left by the misty night, and seem to be fairy curtains hung on every bough.

“The lengthened night elapsed, the morning shines  
Serene, in all her dewy beauty bright,  
Unfolding fair the last autumnal day.  
And now the mounting sun dispels the fog;  
The rigid hoar frost melts before his beam;  
And, hung on every spray, on every blade  
Of grass, the myriad dewdrops twinkle round.”

When the great November wind has passed over the country and stripped the trees of all their foliage, and left them standing like so many gaunt sentinels watching over the wintry nakedness, what numbers of places are exposed to view which in summer time were totally hidden beneath an embowering screen of dense foliage—the winding river, the distant hill, the village church and isolated cottage, which a few short weeks ago were quite shut out from view. On the leafless hedges the birds congregate in great numbers to regale themselves with food from the bounteous store of berries which now are seen on Thorn, Privet, wild Rose, and Holly. The eddying brook bears on its swiftly flowing current many a tiny bark in the form of some withered leaf which the rude wind has blown upon its breast; and on its banks the tall Sedges and Reeds keep up a monotonous moan, played upon by the wintry wind.

As the month advances the sunny days become fewer, and rain falls continuously for some time.

“In the stormy east wind straining  
The pale yellow woods are waning;  
The broad stream in its banks complaining,  
Heavily the low sky raining.”

And the season well merits the epithet of dreary; yet the poet finds something to call him forth to the abiding places of Nature even at this dull season.

“In pensive guise  
Oft let me wander o'er the russet mead,  
And through the saddened grove where scarce is heard  
One dying strain to cheer the woodman's toil.  
Haply some widowed songster pours his plaint  
Far, in faint warblings, through the tawny copse;  
While congregated thrushes, linnets, larks,  
And each wild throat, whose artless strains so late  
Swelled all the music of the swarming shades,  
Robbed of their tuneful souls, now shivering sit  
On the dead tree, a dull despondent flock;  
With not a brightness waving o'er their plumes,  
And nought save chattering discord in their note.”

—T. S. J.

## FERN-LEAVED PARSLEY.

No crisped, crested, or finely divided Fern can vie with this Parsley in the density of its crests and curls. So finely divided are its parts, that this Parsley is comparable only with the finest of our wood mosses. A plant of this Parsley in a 6 or 7-inch pot would be admissible as a table plant, and befitting a prominent place in an arrangement of ornamental-foliage plants; whilst for association with ornamental foliage and flowers in a cut state I know of no more suitable groundwork than that formed of its green moss-like leaves. Its colour—a pleasing light green—renders it much superior as a garnishing plant to the ordinary varieties of curled Parsley, and its

quality is such as to befit it for every culinary purpose; for it should always be borne in mind that Parsley, unlike some other garnishing plants, must not only be good to look at, but must possess culinary properties. I had doubts of the free growth of this delicate-looking Parsley, but these have disappeared, for a row of it 24 yards long is as free in growth as the 300 yards length of the ordinary kind.

It is often difficult to provide a full supply of Parsley during the winter and spring months. This may be in a great extent effected by sowing an extended breadth. Nothing weakens a plant so much as close cropping—continually picking the growths as they appear.—A.

## FLOWER SHOWS AND THE PUBLIC.

SOME people, happily only a few, would have it believed that public interest in flower shows is generally decreasing; but such opinion is founded on some local and temporary failure, caused by official mismanagement, and not unfrequently from pandering to class prejudices instead of studying the general welfare of the society. One cause of the occasional apparent decrease of interest taken in old horticultural societies in towns is the extension of exhibitions to small country places. Taking the counties of Durham and Northumberland as an example of the changes during a few years, I believe over sixty exhibitions are there held annually, whilst up to about 1835 there was only one—viz., at Newcastle, with branch meetings in Morpeth, Berwick, Alnwick, Darlington, Hexham, and elsewhere. The unbeliever in the increased taste for horticulture should take a survey in the suburbs of our towns, where, even under great atmospheric difficulties, he will find a host of gardeners labouring hard and successfully.

I will turn from generalities to the subject at present most interesting to myself—viz., the Newcastle-on-Tyne Botanical and Horticultural Society, where I share the office of Honorary Secretary, which you know confers the privilege of pleasing nobody, but I hope these notes will meet a better fate. The Newcastle meetings have been held annually, once or oftener, since the year 1824. Of course their ups and downs during a lifetime of fifty-two years have not been few, but such being of little interest to your readers generally I will refer only to what has taken place this autumn. This Society seemed for some years to be decaying, till this season it became almost a question whether it were better to allow it to die a natural death. The general remark was, "It must go; Newcastle has no taste for flowers, and will not support such a society;" but two members of the Committee differing from this opinion were in October of this year appointed Honorary Secretaries to re-organise the management, since when (only six weeks ago) the income from subscriptions has risen from nominally £190 to £730, contributed by over 1650 annual subscribers, in addition to offers of special prizes (for the spring show on the 21st and 22nd of next March) from nurserymen, &c., residing in every part of England, also from many continental growers. From the manner in which our efforts have been received by the public I feel sure that a much greater accession of income is to be expected, so that the Newcastle Society has prospects of being worthy of a town and neighbourhood containing over half a million inhabitants. This success, especially in so short a time, clearly justifies my previous assertion, that public interest in horticultural exhibitions is not dead, but that when indifferently supported the cause is generally to be found in the mismanagement of the shows, and not in the apathy of the public.—W. J. TAYLOR, *Rye Hill*.

## THE GREAT BERKSHIRE ROOT AND VEGETABLE SHOW.

MESSERS. SUTTON have so increased their building and made it so thoroughly adaptable for their purpose, that even those who have wondered at the Exhibition in past years are fain to confess that this is immeasurably beyond those that have gone before, and those who have not seen it may form some notion of the extent from a few facts. The total number of entries were 1300 as compared with 870 last year. The main part of the Show was held in a large room, 195 feet long by 60 broad, where two thousand roots were shown from all parts of the kingdom. Some of the mammoth Red Mangolds were 3 feet in length, and others weighed upwards of 60 lbs., one entry of twelve roots weighing 430 lbs. The value of the Champion Swede may be gathered from the fact that for nineteen years it has won the two cups, value twenty guineas each, given by Her Majesty the Queen for the best roots grown in the counties of Berks and Bucks, besides

other valuable prizes. In rooms opening upon the large one were placed the White, Greystone, Purple-top Mammoth, Yellow-flesh Turnip, some most beautiful samples coming from the far-off "Kingdom of Fife," probably the handsomest roots in the Show. Of Potatoes a most admirable collection was staged, large in quantity, and for the year most excellent in quality. It was easy to see from the specimens of Sutton's Red-skin Flourball why complaints are sometimes made, for some which I have seen in other places were no more like those exhibited here than a Dutch cheese is like a Wiltshire. These were round, symmetrical, and weighty, whereas in other cases I have seen them mis-shapen, light, and deep-eyed. Sutton's Magnum Bonum has proved itself a most wonderful cropper; one exhibitor, Major Troyte, showing 27 lbs. grown from 1 lb. of seed, while Hundred-fold Fluke has again proved itself most thoroughly disease-resisting. Mr. Fenn exhibited a small but handsome collection of his seedlings, many of which seemed very promising, and were set up with that extreme regard to neatness and precision with which he always exhibits his productions.

The collections of vegetables exhibited by Mr. Walter, M.P., of Bearwood, Mr. Southby, and others were extremely creditable, the first prize going to Mr. Walter, and containing fine samples of Sutton's Snowball Turnip, Sulham's Prize Celery, Sutton's Golden Globe Savoy, Scrymger's Giant Brussels Sprouts, Veitch's Autumn Giant Cauliflower, Sutton's Beet, Telegraph Cucumber, Trophy Tomato, &c. The classes for Onions, Carrots, and Parsnips were also remarkably well filled, and no one seeing them would have considered that the season had been an unfavourable one, so symmetrical and clean were they. Altogether I think the Messrs. Sutton must be thoroughly satisfied with the result of their exertions, and with the confidence reposed in them by their customers.—LE ROI CAROTE.

## GARIBALDI STRAWBERRY.

IT will still be fresh in the minds of some readers of this Journal of a statement I made some years since, that Garibaldi and Viscomtesse Hericart de Thury were identical. This was immediately contradicted by the raiser of Garibaldi, and subsequently I apologised for my rash statement, explaining that a local nurseryman had led me to believe that the two names were synonymous. I fear that corruption of names is common amongst Strawberries. For example: An old variety of Strawberry was recently changed to Dumbarton Castle; another old Strawberry known as Brown's Wonder is being sold at 20s. per 100 under the name of Balm's Seedling. Again, a large quantity of Admiral Dundas Strawberry has been supplied for President, the vendor declaring they were the same; but at the same time he had not plants of President. Comment on such practices would be useless further than saying it is a pity that anyone should be allowed to continue the dishonesty.

I have devoted much time to Strawberries, comparing varieties, &c., and raising seedlings, therefore I do not write without some knowledge on the subject when I state that Garibaldi is as distinct from Viscomtesse Hericart de Thury as the Elton Pine is from President. Even a person with his eyes shut may tell the difference, as the flavour of Garibaldi approaches to that of Keen's Seedling, which cannot be said of the Viscomtesse. Garibaldi has the property of bearing more fruit (when other trusses are in bloom) than any other Strawberry in cultivation.—W. THOMSON.

## EARLY WRITERS ON ENGLISH GARDENING.

No. 22.

SIR WILLIAM TEMPLE.

SIR WILLIAM TEMPLE was the son of Sir John Temple, and was born in 1628 at Blackfriars, London. He commenced his education under his maternal uncle, the learned Dr. Hammond, continued his studies at Bishop Stortford School, and concluded them under Dr. Cudworth at Emmanuel College, Cambridge. From the University he proceeded abroad, and at the Restoration was chosen a member of the Irish Parliament. In 1665 he went on a secret mission to the Sovereign Bishop of Munster, in Westphalia; was employed afterwards in forming the triple alliance between Sweden, Holland, and this country, and became resident minister at the Hague, in which capacity he promoted the union between the Prince of Orange and Princess Mary. In 1679 he became Secretary of State, but in the following year retired from office to his country seat, Sheen in Surrey, where he was repeatedly visited by his Sovereigns, Charles II., James II., and William III. He died in 1699 on the 27th of January.

His works have been published in two vols. folio, and four

vols. 8vo. In the first volume of them is contained his essay entitled "The Garden of Epicurus; or of Gardening in the Year 1685." This essay is devoted chiefly to inculcate that taste for formal design in gardening which was the prevailing one of his time. When we compare it with the plan given by Lord Bacon in a preceding age, for a similar construction, we find but this difference, that if both plans were reduced to practice, Sir William's would be rather the most mathematical and undeviatingly formal. Sir William Temple's *beau idéal* of a garden is that of a flat or gently sloping plot of an oblong shape stretching away from the front of the house, with the descent to it from a terrace running the whole length of the house, by means of a flight of steps. Such a garden, he says, existed at Moor Park in Hertfordshire, formed by the celebrated Lucy, Countess of Bedford, one of the chief wits of her time. It was on the slope of a hill, with two terraces rising one over the other, and united by a magnificent flight

Fig. 70.—Sir William Temple.

of steps. A parterre, wilderness, highly ornamental fountains, statues, alcoves, and cloisters, were its prominent parts and ornaments.

When he descends to more practical speculations he is seldom in error, among which we may specify his observations upon planting Peaches in the north of Britain, which experience has demonstrated to be correct. Sir William improved his knowledge of gardening during his stay at the Hague. He introduced several new fruits, especially of Grapes. His name still attaches to a variety of the Nectarine, and everyone knows the Moor Park Apricot. He had a garden at his seat at Sheen in Surrey, to the good cultivation of which Evelyn bears this testimony—"The most remarkable things are his orangery and garden, where the wall-fruit trees are exquisitely nailed and trained." Nothing can demonstrate more fully the delight Sir William took in gardening than this direction in his will, that his heart should be buried beneath the sun dial of his garden at Moor Park, near Farnham in Surrey, affording another instance of the ruling passion unweakened even in death. Nor was this an unphilosophical clinging to that which it was impossible to retain, but rather a grateful feeling common to our nature. In his garden Sir William Temple had spent the calmest hours of a well-spent life, and where his heart had been most peaceful he wished its dust to mingle, and thus at the same time offering his last testimony to the sentiment that in a garden

"Repose is secured and life unnoted slides away."

Temple's love of gardening peeps out in all his letters. Writing in 1688, Evelyn says he went to see Sir William's orangery and gardens at Sheen, and that he observed the trees

were "most exquisitely nailed and trained." This excellence of practice we attribute to his gardener, for though he notes with approbation Epicurus living in his garden, yet it is with the addition that such a life promotes "tranquillity of mind and indolence of body."

## ALFRETON HALL.

THE RESIDENCE OF C. R. PALMER MOREWOOD, Esq.

DERBYSHIRE is noted for its hills and dales—in fact, there are few counties in England which present such an irregular surface. The northern and southern parts of the county are in striking contrast with each other. The southern is not particularly remarkable for its undulating scenery, for south of Derby we meet with long tracts of tableland, while the northern part of the county is distinguished in an eminent degree by its long and continued succession of bold hills, romantic dales, and beautiful valleys. Stretching northwards from Alfreton Park the landscape rises before the vision in rugged and majestic grandeur. In this district it begins to gently rise into hills, which in their progress to the north swell gradually into mountains. These extend in one great chain, usually termed "The Backbone of England," to the southern extremity of Scotland. They first divide Yorkshire and Lancashire, then entering Westmoreland they spread over the whole face of that county and a part of Cumberland and Northumberland; after this they contract again in a ridge or chain, and form the limits between Cumberland and Northumberland; continuing their direction northward they enter Scotland. The south and east parts of Derbyshire are pleasant and fertile, producing most kinds of grain, particularly Barley. The north-west part, so well known by the name of "The Peak," is a hilly tract abundantly rich in minerals, and the intermediate valleys are clothed with grass. The mineral productions of Derbyshire embrace nearly every species of subterranean wealth, but coal, lead, iron, and marble are those which chiefly engage the industry and enterprise of the inhabitants. Ironstone is found in the coal stratum, except at Chinley Hills. The ironstone beds near Alfreton and Chesterfield are the most valuable. The celebrated Alfreton or Butterly ironworks are very extensive; the massive castings executed here have rendered the ironworks of Derbyshire universally celebrated.

The town of Alfreton is pleasantly situated on the brow of a hill. On the western side of the town there is a beautiful and well-wooded park, which has been the seat of the Morewood family for more than a century. The site of the mansion is well chosen, being on a gentle eminence, which is seen to great advantage from the Derby road. It is in the Grecian style of architecture, and presents a noble and imposing appearance. We enter the grounds by a comfortable lodge just on the outskirts of the town, snugly enconcealed amid many-tinted trees. Passing through an avenue of fine old Beeches we reach a large open space of lawn on the north front of the mansion. Many handsome deciduous and evergreen trees are dotted in different positions on the grass. In one place we pause to admire the gigantic proportions of a Purple Beech, then the symmetrical outline of a variegated Holly, of which there are many fine specimens; next a noble Sycamore, fine Cedars of Lebanon, and towering Oaks and Elms. The park is separated from the pleasure grounds by a judiciously arranged sunk fence, which completely conceals the point of junction. Here we obtain some fine views of the Derbyshire hills. To the right is the scattered village of Shirland, and in the circle of the horizon are the hills of Ashover, Ogston Hall, Crich, and Crich Cliff. The latter place is said to be the highest hill in the county with the exception of the High Peak. On its summit there is an observatory called Crich Stand, which was erected in 1788, and rebuilt of stone in 1851 by the late Francis Hart, Esq. It is 955 feet above the sea level, and from the top the eye is gratified by wandering over several counties and into the Principality.

We noticed in passing along the various walks that Mr. B. Marks, the gardener, devotes special care to the filling and arranging of the plants in the various vases. These were broad and shallow, fringed round the margin with plants of drooping habit, while those of more upright growth occupied the centre. The flower garden is on the east side of the mansion, and was laid out in geometric style. All the beds were filled to overflowing, and presented a glorious floral blaze. The single plants of *Ricinus* elegantissimas in the round beds had a striking effect, and took away the sameness. Subjoined is a plan of the beds and the style of planting. This flower

garden is bounded on the north side by a range of glass houses, consisting of vineries, conservatory, and fernery; on the east and west sides by clumps of evergreens and other tall trees, and the south side is open to the landscape. From the lower

side of the flower garden there is a path which communicates with the carriage drive, flanked with standard Roses and backed-up with fine clumps of Rhododendrons, while to the left is a handsome miniature lake.

Fig. 71.—GARDEN PLAN AT ALFRETON HALL.

- 1, Large vase.
- 2, Centre variegated Geranium, with a band of *Colens Verschaffeltii*, edged with Golden Feather.
- 3, Centre Geranium Waltham Seedling, with a band of white Verbena, edged with blue Lobelia.
- 4, Centre Geranium Amy Hogg, with a band of lavender and white-striped Verbena, edged with blue Lobelia.
- 5, Centre single plant of *Ricinus elegantissimus*; bed planted with *Iresine Lindeni*, edged with Golden Feather.
- 6, Striped Petunia, edged with blue Lobelia.

- 7, Variegated Geranium, edged with Lobelia.
- 8, Geranium Cloth of Gold, edged with Lobelia.
- 9, Geranium Christine, edged with Lobelia.
- 10, Purple King Verbena, edged with *Dactylis glomerata variegata*.
- 11, Prince of Orange Calceolaria, edged with Lobelia.
- 12, Geranium Lady Callum, edged with blue Lobelia.
- 13, White Verbena, edged with *Colens Verschaffeltii*.
- 14, Crimson King Verbena, edged with *Mesembryanthemum cordifolium variegatum*.
- 15, Gold and Bronze Geranium, edged with blue Lobelia.

Turning into the range of glass houses, the first was a late vinery with a collection of mixed plants growing underneath the Vines. The second house was a conservatory with fine

Camellias planted in the back border. On the stage I noticed well-grown Pelargoniums, Fuchsias, and such other greenhouse plants as are generally found in well-regulated establishments.

The next house was a vinery devoted to Muscats. Here also was a mixed collection of plants, for so great is the demand for flowering and fine-foliage plants for the embellishment of the mansion, that Mr. Marks has to economise every inch of space and make the best of his glass accommodation. With regard to the Vines we cannot speak in flattering terms. As the worthy proprietor is but a young gentleman, it would afford him and his able gardener the most satisfaction to have the Vines rooted out and start with a fresh set. We have known these Vines for more than twenty years, but never saw them with a crop of Grapes worthy of the trouble they incur and space they occupy. The last house in the range was the fernery. Here we observed some fine plants of *Blechnum Corcovadense*, *Pteris elegantissima*, *Neottopteris nidus*, *Dicksonia antarctica*, *Adiantum concinnum latum*, *Adiantum cuneatum*, &c.; also Palms and Begonias.

Leaving these houses we crossed the grounds in the direction of the kitchen gardens. Just outside the garden gates there was a pool of Nymphæas with their lovely blossoms floating on the surface of the water. Passing into the walled kitchen garden, which is just two acres in extent, but like all other gardens of this class, there are some large strips outside the walls. On the lower side the centre walk there was a ribbon border planted as follows:—Front row *Lobelia speciosa* and *Dactylis glomerata variegata* alternate, second row was a pink Verbena, third *Geranium William Underwood*, and the last Dahlias.

We next entered a range of houses, the first of which was for Peaches. There was a good crop of Royal George, Noblesse, and Grosse Mignonne. The second house was also Peaches; the crop was moderate, but the fruit fine in quality. The third house was an early vinery, chiefly Black Hamburgs and Muscat Hamburgs. The fruit was ripe by the first week in June, and though the bunches were not quite so large as we are sometimes accustomed to see, yet they were well finished and such as are always acceptable at a gentleman's table. The next house was a Muscat vinery with Gardenias on the stages. Standing a little distance from the latter was a span-roofed Pine house containing some good fruiting Pines, besides some fine specimens of *Caladiums*, *Dracenas*, and *Cissus discolor*. In a span-roofed house the Cucumbers were in good bearing condition, and we noticed specially such sorts as Telegraph and Tender-and-True doing well. In the adjoining Melon house the plants were flourishing, and Read's Hybrid and Queen Emma appeared favourite sorts. Besides the Melons and Cucumbers there were hosts of Achimenes, Coleuses, and other plants, all required for the decoration of the mansion.

The Apricots on the walls were rather a failing crop. In the various quarters in the kitchen garden Peas and other culinary vegetables were in good condition and plentiful. We were pleased to notice the marked improvement of the gardens generally since they came under the management of Mr. Marks, and have no doubt if the like progress is maintained in the future that has been observable during the last three or four years that they will soon compare with the best gardens in the district.—Q. R.

### MESSRS. JACKSON & SON'S NURSERIES, KINGSTON-ON-THAMES.

WHETHER it be to the plant-exhibitor, botanist, or florist, this establishment is always attractive. The name of this firm has become very familiar from the many victories won at the great metropolitan and other large shows. No other nurseries are richer in Cape and New Holland plants, and in few places are they grown in greater profusion; but these are not the only plants that are grown well here, for florist flowers receive more than ordinary attention, and the show house is particularly gay just now with a fine display of *Chrysanthemums*. Situated in one of the main streets of Kingston it presents one mass of bloom to passers-by, and many a hasty pedestrian stops to admire the gayness of the interior. At the time of my visit these plants were just at their best, and were equal to any I have seen this season.

MESSRS. JACKSON have received some new Japanese varieties from Monsieur Lemoine, and it is to be regretted that some of them were not shown at South Kensington at the last meeting, where they would doubtless have been certificated, especially Fulton, a bright golden yellow, very pleasing, quite 6 inches across and of great substance, in the way of Elaine; Fulgore, quite a novelty among the Japanese sorts both for shape and colour, somewhat the colour of the old Ariadne; La Nymph,

Nuit d'Hiver, M. Lucien Barthere, and Lacinatum. These were the most noticeable of the new varieties. Of the good older sorts I noticed *Grandiflora*, Chang, Baronne de Prailly, quite 9 inches across; James Salter, Elaine, Magnum Bonum, Bismarck, Fair Maid of Guernsey, the best for decorative purposes, for it can be cut with such a length of stalk, and is one of the freest to bloom; Apollo, and Bronze Dragon. Among the incurved varieties were both the Golden and White Beverleys, Mrs. G. Rundle, and her sports—Mr. G. Glenny and Mrs. Dixon. What a pity these sports are not designated Primrose Mrs. G. Rundle and Golden Mrs. G. Rundle, for Mrs. G. Rundle is known and valued by all growers, and her sports are valuable additions, especially Mrs. Dixon, for here we have the colour of *Jardin des Plantes* combined with the symmetry of the parent, Mrs. Rundle. Empress of India, Prince Alfred, Venus, Eve, which I never saw better; Pink Perfection, *Jardin des Plantes*, White Globe, Golden John Salter, and Princess Teck, this last a grand late variety. Triomphe du Nord and Mazeppa are two good reflexed varieties, and among the Anemones are Gluck, Lady Margaret, and Bijou.

Another house contained excellent samples of Orchids, among which were *Phalanopsis Schilleriana* with leaves 15 inches long, *P. amabilis*, *P. grandiflora rosea*, and *P. Lüddemania*, all in fine health, and showing flower spikes; *Oncidium Weltoni*, *Dendrobium formosum giganteum*, *Saccolabium retusum*, and a batch of many dozens of *Cypripedium niveum*. In the same house were three very large plants of *Platycerium grande*, and an improved form of crested *Pteris*, raised by Messrs. Jackson, and named *P. magnifica*. In the cool Orchid house was a very fine plant of *Celogyne cristata*, with large plump growths, attributed to the cool treatment it receives; it certainly looked remarkably healthy and thriving. There were also here good examples of *Odontoglossums*, *Cattleya Mossii*, *Epidendrums*, *Vandas*, &c. Parallel with these houses is a large stove, in which are grown *Alocasias*, *Crotons*, *Dracenas*, *Dieffenbachias*, *Ixoras*, *Marantas*, &c., and here too are many of the large specimen *Allamandas*, *Dipladenias*, *Ixoras*, *Bougainvilleas*, *Eucharis*, &c. Two large houses are filled to overflowing with *Heaths*, *Pimeleas*, *Aphelexis*, *Phenocomas*, *Staticee*, *Dracophyllums*, *Genetyllis*, *Azaleas*, and other greenhouse-flowering plants, ranging from a foot to 6 feet through, from the quarter and half specimen size to full grown "elephants." Another house, running at right angles with these last, is an intermediate house, rarely kept above 50° to 55°, and there were *Vandas*, *Aërides*; *Dendrobiums nobile*, *Wardianum*, *crassinode*, *Parishii*, and *Falconeri*, all in fine health, and with extraordinary large new growths. In this same house was a vast number of *Anthuriums Scherzerianum*, from plants that would measure 4 feet through to small pieces in thumb pots. I noticed a healthy plant of the white variety about 18 inches through. There were also very fine plants of *Arucaria Rulei* and *Platycerium alciorne major*, a very robust and erect-growing variety of *alciorne* with much darker fronds.

Three new pits have recently been erected, each 127 feet by 13 feet. One is entirely full of Show and Fancy *Pelargoniums*, strong and stocky, including great quantities of Kingston Beauty, Mrs. Bradshaw, Mrs. Lewis Lloyd, Chas. Outram, Leopold, The Moor, and Eva Baker, all new forcing decorative varieties. The other pits contain *Bouvardias*, *Heliotropes*, double *Primulas*, *Cyclamens*, and winter-flowering *Begonias* in vast numbers. In a small house devoted to Ferns there were growing large quantities of *Adiantum farleyense* and all the leading kinds, while of British Ferns their collection numbers over two hundred species and varieties.

There is also a large *Camellia* house; the *Camellias* planted out, and just coming in bloom. A couple of other houses, which contain a thousand *Azaleas* in 48-sized pots, small *Camellias*, *Epacris*, and winter-blooming *Ericas*, and a corner for *Todeas*, *Trichomanes*, and other Filmy Ferns; and many other objects deserving being recorded, but time and space forbid.—J. W. MOORMAN.

### OUR BORDER FLOWERS—SWALLOW-WORTS.

WE are indebted to North America for the hardy herbaceous Swallow-worts we possess. They are not what we call choice border flowers, yet where variety and change are sought after they are desirable. Being strong growers they are well adapted for large borders, open spaces in shrubberies, and other out-of-the-way places where choicer plants will not live. *Asclepiases* will bear partial shade, but they enjoy light and

sunshine; they are impatient of stagnant moisture, but thrive well in a light free soil, a mixture of sandy loam, peat and leaf soil best meeting their requirements. The place intended for their reception should be well broken up to a depth of 18 inches or more, and the compost be well incorporated with the soil. They should be planted firmly, and being tall-growing plants they require staking to prevent them being broken with the wind. When once established they will last many years. They are increased by seed sown in the spring, and division when growth has commenced.

*Asclepias syriaca* appears to have been imported in 1629, but has not found much favour amongst us. In its native home it is said to be very odiferous, charming the traveller when passing through the woods at eventide; it is also said that it is eaten as a vegetable by the inhabitants. The pods afford cotton, which the natives collect to fill their beds with. Parkinson says, on account of the silkiness of this cotton it bears the name of Virginian silk. *Asclepias tuberosa* is the most frequently met with in cultivation, but it is by no means a common plant. There are other kinds enumerated, and which are worthy of being added to collections of "old and rare" plants.—VERITAS.

### POTTING.

[As a "YOUNG GARDENER" doubts the necessity of being so particular about placing drainage in flower pots and of the little details of potting frequently recommended, let him and other young gardeners read the following, and "little details" will not then, we trust, be considered too trivial for adoption. —EDS.]

Or all the numerous operations which come within the range of the gardener's art, that of potting and shifting tender plants from one pot into another must be regarded as one of the most important. A volume could be written on it without exhausting its details or exaggerating its importance in its relation to the numerous varieties of plants and fruits now cultivated in pots. If in anything in gardening "practice combined with intelligence," be not necessary, certainly it is not in potting. By potting we do not merely mean the mechanical operation of surrounding the roots of a plant in a pot with soil. A mere machine might possibly be invented to do that. It might even, perhaps, be taught to a Saturday Reviewer!

Not only does every family and genus of plants require different treatment in this respect, but each species and variety requires to be studied, and the potting adjusted to its peculiarities of constitution and growth. The intelligent observation and sound reasoning of the cultivator must be carefully exercised in the performance of this important operation, or high cultivation need not be looked for as a rule. And very much as has the progress of horticulture depended on the observation or notice-taking of practical men, we question if from any other source improved practice in cultivation has resulted so much as it has from the observations and deductions of practitioners at the potting-bench. However the fact can be accounted for, it has come within our knowledge that men who could discourse eloquently on the science of horticulture, and profess to teach the sound principles of all its branches, make a most complete bungle of potting or shifting a plant, and succeed chiefly in violating every principle on which the health of their subjects depends. In very many instances the practitioner has had no navigate his way to success with next to no extraneous aid, and this forcibly applies to the potting of plants.

We have often thought it a pity that in purely botanical serials, and in the very interesting botanical descriptions of new plants which appear in gardening periodicals, the botanist does not condescend to tell us how much he knows of the soil and other conditions in which plants are found thriving in native homes. This is to be regretted, seeing that they have opportunities of learning this which gardeners cannot have, and which plant-collectors do not always attend to. The consequence is, that the "right way" has to be found out by the experiments and observations of practical men; and is it surprising that at first they miss the way? It is more surprising that they should be sometimes sneered at for the first failure or two.

In most instances pots are a necessary evil. This being the case, it is of a paramount importance to mitigate the evil as much as possible. By way of throwing out a few hints calculated to be useful to beginners at the potting-bench—among whom we would include our scientific friends who may try

their amateur hands at this operation, by way of relaxation perhaps—we would remark that the first thing to be considered in potting a plant to be placed in a glass house is that in nearly every respect it is being placed under circumstances that are thoroughly artificial. The space for its roots is unnaturally restricted, and contains, comparatively speaking, but a few handfuls of soil, which, along with the roots, is exposed to the drying influence of air, not only on the surface, but at the bottom and sides of the ball as well. This exposes the plant to be constantly and rapidly robbed of the moisture necessary to its existence, and much of the food supplied to it within the compass of its pot. This unnatural loss has as constantly to be made good by large supplies of water artificially supplied to soil in the very artificial position of being in a pot. This state of things has a constant tendency to call into play a host of other evils which have to be carefully obviated in the choice of materials for, and in the operation of, potting. It being necessary to administer copious supplies of water almost daily, and sometimes oftener than once a day, the two most prominent and destructive conditions incident to such a necessity are those of stagnant water and the rapid decomposition of the organic substances in the potting material. To some extent these evils are dependant on each other, and are nearly always in existence at the same time.

Perhaps the draining or crocking of pots may at this era of horticulture be considered too common or too trifling a subject to dilate on with profit to readers. Good cultivators do not regard any point trifling, and we are content to submit our verdict to the most successful growers when we say that the draining lies at the foundation of successful pot-plant culture, and that it is one which, if not properly performed and adjusted to the nature of individual plants, will thwart the most careful and correct attention to all other points of culture. Not only so, but we are convinced that the carelessness and unbusiness-like way in which it is performed in very many instances warrants that its importance should be made very prominent; and in a long and extensive practice we are now more convinced than ever that more ill-health and disease and death are caused by inefficient drainage of pots than by any other cause, or perhaps all causes put together. Is it not, therefore, strange, as Mr. Speed of Chatsworth once put it in these columns, that the crocking of pots is very often intrusted to the boy or woman of the establishment? It is an operation which we have long ago ceased to delegate to such hands except in the case of the most common plants that have to be in pots but for a very short time. We should much rather see the foreman of the establishment doing this work than the boy when plants of any importance are concerned. This much by way of impressing the importance of the drainage of pots on the minds of the careless and inexperienced.

It is not only nor so much on the quantity of crocks put into a pot, as on their proper adjustment, that success in carrying off all superfluous water from the soil in a pot depends. A pot half full of crocks may not be so well drained as another may be with only an inch. In all well-ordered gardens where pot plants are grown there should be three or four different sizes of crocks, sizes that may be termed for ordinary purposes, inch, half-inch, and quarter-inch crocks, which, in breaking up a mass of crocks, can be easily assorted by using sieves of different sizes. These should be clean as the pots themselves, and all dust should be separated from them. Speaking generally the largest of them should form three-fourths of the drainage of large pots, and the other fourth, consisting of the second size, should be blinded with the smaller, and over all a little dry moss, or a portion of the most fibry of the soil, should be placed. In a moist stove where plants have to be heavily syringed, or in the case of delicate hardwooded plants, a 14 or 16-inch pot should never have less than 3 or 4 inches of drainage thus arranged; while in the case of special and shallow-rooting plants it should be double this amount, or even more, just as the tendency of the plant is found to be surface-rooting. An 11-inch or an 8-inch pot will be sufficiently drained with a lesser depth of crocks in proportion to its size; 2 inches and 1½ being generally sufficient, but always arranged with the same scrupulous care. This rule applies with augmented force to all plants that are plunged, such as Pines, and to plants of delicate constitution, whether they be soft or hardwooded. The concave side of the crock or piece of broken pot should be placed undermost in placing it over the holes in the bottom of the pots, for, if placed the other way, it too often fits too closely to the pots to admit of the ready passage of the superfluous water. Thus arranged, the soil used in potting does not

get down amongst the crocks and prevent their serving their intended end.

If anyone wants to prove—who has not done so already—that this is a trifling part of plant culture, let him take two Heaths, Azaleas, Camellias, or even a Pine plant, or a Pelargonium, and drain the pot for one of them as above described, and the pot for its fellow by carelessly—a by no means uncommon practice—rumbling into the bottom of the pot a few large and ungainly pieces of dirty pot or brick, and subject the plants to the same treatment otherwise, and they will be witnesses to results so diverse that the matter will soon come to be regarded as of paramount importance; and they will not consider that we have insisted on the strict observance of a trifling point of culture. We might almost say that what the foundation is to the structure, the proper draining is to the successful growth of plants in pots.

Only the other day we were engaged in shifting some Azaleas which had their pots properly drained two years since, and on turning them out of their pots the crocks fell from the bottom of their balls as clean as the day they were put in. The roots of these plants were in the most perfect health, ready for increased feeding ground. In the case of others which had a few large pieces of crocks pitched carelessly into their pots, the passage for water was next to entirely filled up by the soil working down among the crocks to the bottom of the pots. The consequence was that half the ball stuck in the pot, and it was a soured mass of peat, in which the roots had perished, if ever they had entered it at all. Such crocking in conjunction with old unwashed pots is in time certain death to plants, if the evil is not timeously put right.—(*The Gardener*.)

### EUCALYPTUS GLOBULUS.

INFORMATION being asked as to its hardness, I am enabled to state that I was presented with a specimen in the spring of 1875, which I planted in the centre of a flower bed in my garden. It was then about 6 inches high, but is now at least 8 feet, with a stem 6 inches in circumference, and very healthy. It suffered somewhat during last winter from the frost, but not to any considerable extent. My garden is at the rear of the house, which is on the seashore facing the east, so that it is partially sheltered; but it is exposed to the north and north-west winds, which we get in this locality with no unsparing hand.—W. H. DIGGES, *Sandymount, Dublin*.

IN reply to Mr. G. Abbey, in your *Journal* of November 16th. In 1869 I raised a plant from seed, which when it was about 2 feet high I planted in a south border. It was cut down by frost to a single leaf. I then repotted it, tied up the single leaf to a stick, and placed it in a small hothouse; there it very soon recovered itself, and grew into a tree too large for me in less than two years. It still lives in the large conservatory of a friend, but will, I suspect, soon outgrow him too. Whether it could now be hardened so as to stand frost is an interesting question.—S. C.

I AM glad to see that your valued correspondent, Mr. Abbey, has drawn the attention of your readers to the possibility of acclimatising this fine plant, as I firmly believe that it can be done by those who possess both skill and space, but I think it must be protected for two or three winters. I have grown it for some years without bottom heat. Sowing the seeds in the open garden in April, planting out the seedlings when a few leaves appear; they grow about 2 feet. In the autumn I pot them in common garden soil, and place them in an old Cucumber frame, and the following spring plant them out where I want them to stand. They grow to about 7 or 8 feet in height; I then destroy them, as I have always assumed that they would not winter without protection, which I have no space to afford them. But in future, as Mr. Abbey seems to consider that there is some hope of success, I shall try what I can do in my small way to preserve them. Is the globulus and globosus the same? The leaf of the latter is much darker.—G. D.

[There is no species named globosus. It must be a misnomer for globulus.—Eds.]

WE have here some very fine specimens of the *Eucalyptus*; they are about six years old, and have stood unprotected for five years. Some of them have attained the height of 35 feet, with stems 18 inches in circumference, and appear quite healthy. They were grown in pots the first year, which in my opinion was a mistake, for the roots if crippled when young

do not gain sufficient hold of the soil to support the heavy heads of the trees. It may be observed that the *Eucalyptus* sends down a strong tap-root, which is no doubt its chief support, and if this root is stopped by coming in contact with the bottom of the pot it will never again resume its former course, even when the tree is planted out. I have proved this by the above specimens, for had it not been for the aid of some large stones placed round the bases of the trees they would have been overturned by the storms. The seeds should be sown where the trees are required to grow, protecting them with spruce branches for the first winter.

I have sown seeds of *Eucalyptus* in different situations, and have found the young plants do admirably in all cases; but those in sheltered places have attained a larger size, but do not appear so hardy as those in exposed positions. Most of the seedlings have grown to the height of 2 feet during the first season, and have withstood 8° of frost on several occasions this winter unprotected. The seeds were sown on the 20th of April in small patches of well-prepared ground, placing about twelve seeds in each patch, and covering them to the depth of half an inch with a compost of sand, loam, and leaf soil. I thinned out the seedlings, leaving three of the strongest in each patch, which will remain through the winter. Those that were removed I have placed in pots and purpose using them as foliage plants in the flower garden next summer.—ANDREW CAMPBELL, *Muckross Abbey, Killarney*.

### BLUE GEM VERONICA.

OBSERVING for the last several weeks in the *Journal of Horticulture* favourable remarks on the above plant, I have thought it just possible that its origin might not be known to some of your readers, and who may like to know a little of its history.

I must go back to the spring of 1868, when I discovered growing in my forcing house in a pot, where an Azalea was the principal occupant, what I thought at first to be a weed of some kind, then in its first pair of small seed leaves, but seeing that it differed somewhat in general appearance from most weeds with which I was acquainted I let it remain till the seed leaves had developed and the second pairs of leaves made their appearance. Then I potted it into a thumb pot and looked after it more carefully, soon discovering it to be a seedling *Veronica*. During the spring and summer of 1869 I propagated it as much as it would allow of, with the exception of a few plants which I grew on for specimens, treating them liberally both in pots and open borders. Finding it constant to its original habit I began to exhibit it in August, and took five first-class certificates for it at various horticultural exhibitions with plants only two or three days previously taken from the open borders. The last place of its being exhibited was before the Floral Committee of the Royal Horticultural Society, who awarded it its honours without a dissentient voice. Ultimately I sold the stock to Messrs. Cripp & Son, nurserymen, Tunbridge Wells, who sent it out in trade order the following spring.—H. W. WARREN, *Gardener to the Earl of Portsmouth, Hursbourne Park, Hants*.

### CUCUMBERS.

THE past season has not been one of the best I have witnessed for growing Cucumbers. In the first place we had an unusually cold spring, with but very little sun, and this weather lasted far into what should have been summer; then came a sudden change to exceedingly hot weather, rendering it difficult to supply the plants with a sufficiency of water at the roots, and to keep the house at the proper humidity for the health of the foliage. My Cucumber house is about 24 feet in length and 12 feet in width, and as I have a strong demand for Cucumbers it becomes me to grow the sorts which are the most productive. For the purpose of experiment I tried several varieties, planting them the last week in February, and I began cutting early in April. The plants were removed the first week in November.

The first to mention is Nonesuch; not a new variety, but perhaps not so popular as it should be, as I found it an excellent kind, very prolific, and handsome, growing from 18 to 22 inches in length, of a deep olive colour, of good quality, bearing well till the finish of the season. Telegraph needs very little comment, as it is admitted to be a most useful variety, and ought to be grown in all gardens. Tender and True I regard as an exhibition variety, and for that purpose none can surpass it. Cox's Volunteer I found extremely use-

ful; it is a very quick-growing variety, small, but of good quality. Star of the West is a variety in strong repute with market gardeners in this neighbourhood, but it is not adapted for growing in a house. In a span-roof pit, where it had plenty of room to ramble about, it did remarkably well, but it evidently does not like much pruning. The last on my list, but not least, is a variety that I mean to give another trial; it is Osmaston Manor. It has done very well with me, producing some splendid fruit, from 24 to 28 inches in length. I grew Tender and True about the same length, but I must give the palm to Osmaston Manor for flavour. It is also valuable as keeping its colour a long time after growth has ceased—a point of no small importance at the end of the season, when Cucumbers are becoming scarce.

For general use I prefer Telegraph and Nonesuch, for the exhibition table Tender and True, while Osmaston Manor promises to be good for any purpose; but one cannot cut a fresh fruit every day from a long-growing variety when space is limited. Perhaps some other growers will state their experience with different varieties, for the time is approaching when preparations must be made for the Cucumber supply of next year.—J. P.

### NOTES AND GLEANINGS.

A MEETING OF THE DEBENTURE-HOLDERS OF THE ROYAL HORTICULTURAL SOCIETY was held on the 23rd instant. The result was passing unanimously the following resolution:—"This meeting declines to authorise the surrender of the lease of the Garden to the Commissioners on the terms mentioned in the letter of the 2nd November, 1876; and this meeting will not authorise the surrender of the lease unless provision be made for the payment of the debenture debt in full or by instalments, and that a copy of the resolution be forwarded to the Society."

At present a houseful of BOUVARDIAS at Messrs. Veitch's Royal Exotic Nursery, Chelsea, is very attractive, and the visitor cannot but observe the marked superiority of the variety *Vreelandii*; it is the most profuse bloomer, except *Hogarth*, from which it sported. These two are grown in large quantities. A variety named The Bride is of the purest white, and well worth adding to a collection of these plants. Rose Queen is distinct and beautiful. Amongst Tree or Perpetual-flowering Carnations the pure white variety *La Belle* and the flesh-coloured *Miss Jolliffe* are the best in their respective classes, and produce flowers in abundance.

A CORRESPONDENT, writing to us from Merionethshire, states that MANDEVILLA SUAVEOLENS is growing and flowering out of doors at Peniarth without any protection. A plant of it has been so growing for about four years on the south-west side of the house; it is now about 12 feet high, and this year has flowered very well. It is also similarly growing at Bodrhyddon near Rhyll, the seat of Captain Rowley Conway. We shall be glad to hear further as to the hardiness of this sweet-scented climber, and how many degrees of frost it has endured without receiving injury.

We have received from Mr. H. Cannell, Swanley, Kent, trusses of thirty varieties of DOUBLE AND SINGLE PELARGONIUMS, which for size, symmetry, and variety of colours we have never seen surpassed at any season of the year. Some of the pips of the single varieties are nearly 2 inches in diameter, and are stout and of good form, and the double varieties are full and fine. The colours range from pure white to crimson-maroon, and embrace all the tints of pink, rose, cerise, salmon, with orange-scarlet, and a decided dash of yellow in one, which we recognise as *Jealousy*; another variety, "New Life," being bright scarlet flaked with white and rose like a *Carnation*. Such flowers at any season are meritorious, but to have them in profusion during the winter months renders these superior varieties more than doubly valuable; they are in fact indispensable for winter decoration.

Mr. E. BENNET, Rabley Nurseries, writes, "Could any of your readers inform me the name of the person who sent out GARIBALDI STRAWBERRY, or the reputed raiser of it? This might give a clue to its identity with *Viscomtesse Héricart de Thury* or otherwise.—(See p. 467.)"

We have recently admired a number of plants of APHELANDRA ROEZZII, which were raised from seed sown in February last. These plants are in 5-inch pots, and their short vigorous spikes of fiery scarlet flowers are exceedingly rich. Since these brilliant plants can be so easily produced it

is surprising that they are not more frequently seen. They are stove plants of the greatest decorative value, and are worthy of extensive cultivation.

A "CONSERVATORY FOREMAN" writes to us as follows:—"I have recently potted a number of plants from the open ground of *SCHIZOSTYLIS COCCINEA*, and for the next two months they will produce their brilliant flowers in profusion. Few plants are more effective and more easy to grow in large quantities than this. All the cultivation that is required is to plant in good ground in April and pot again in October, and scarlet flowers will be provided for the remaining part of the year."

Few plants give better evidence of the "power of cultivation" than *SEDUM SPECTABILE*. The best variety of this old plant is attractive even when struggling for life, as it were, in the crevices of rocks or in the crowded thicket of the wilderness or neglected herbaceous border; but when well grown—that is, when young plants are raised and planted in good soil, they produce an effect little short of surprising. Never shall we forget seeing some wonderful beds of this plant at Drumlanrig. Many of the flower heads could not have been less than a foot across, and the rosy-pink surfaces of the beds were as level almost as a "glassy pool." Mr. Record, we have noticed, grows this good old plant well at Vintners Park, and it would be useful if he would describe his mode of culture.

SOME small beds at the CRYSTAL PALACE are effectively planted with dwarf evergreens; one from its simplicity may be noted as an example. The centre is filled with *Cryptomeria elegans*, and surrounded with dwarf plants of *Aucuba japonica*; next to the *Aucuba* comes a band of green Box, then a row of *Euonymus radicans variegatus*, the margin being planted with *Golden Feather*. The centre of the bed is not more than a foot in height, and the surrounding rows diminish in height as they approach the margin. The effect of these distinct yet diminutive shrubs thus arranged is quite cheering, and the beds will continue attractive throughout the winter without receiving any attention whatever. They are a great improvement on beds "furnished" with bare brown soil.

THE unsightly patches of BARE GROUND AROUND THE STEMS OF DECIDUOUS TREES on lawns in pleasure grounds have been frequently observed and regretted. Under such trees grass will not grow, but the ground nevertheless need not be bare when a plant so plentiful as the common Ivy will cover it effectively. Ivy is the best of all evergreen carpet plants for planting under trees. A circle of closely kept Ivy 10 or 20 feet in diameter around the stem of an old deciduous tree is peculiarly appropriate, and adds greatly to the ornamentation of the lawn and garden. In covering the surface of the soil in dense shade, the best plan is to plant strong established plants of the common green Ivy at the present time. The plants should be closely planted, and they will speedily form a covering that will last a lifetime. It is an advantage if the Ivy has been established in pots previously to planting under the trees; such plants are now provided in most nurseries.

MR. W. J. TAYLOR writes to us that the NEWCASTLE-UPON-TYNE HORTICULTURAL SHOW was instituted in 1824, and has been held annually for fifty-two years, and he asks if any older horticultural society's show is known.

We have received from Mr. Harrison Weir, Weirleigh, a medium-sized bunch of MRS. PINCE'S BLACK MUSCAT GRAPE. For perfect finish, colour, and bloom an equally good example of this Grape seldom comes under our notice. The berries are also regular in size throughout the bunch, and are of good flavour. The bunch reflects credit on the cultivator.

ON the 9th and 10th the HAGERSTONE ENTOMOLOGICAL SOCIETY held its annual Exhibition at its place of meeting, No. 10, Brownlow Street, Dalston. It was only in 1857 that a few working men interested in insect-collecting discussed, in West Wickham Wood, the desirability of an east-end club for mutual assistance. A club was formed, and now numbers a hundred members. The subscription is but a penny a-week, but with this a reference library has been accumulated. The type cabinet for the collections consists of forty drawers, in which there are now some 15,000 specimens, and the library and collection together are insured for £200. All through the year the Society meets every Thursday, and many points of practical importance (some of them bearing on "the theory of evolution" put to the test by breeding) have been discussed. Among the ways in which members of the Society have done valuable work may be mentioned the preservation of the avenue of Elms in Victoria Park from insect ravages by a

knowledge of exactly how to proceed in dealing with the foe. Although this and several such societies do not obtrude themselves on the scientific world, they still, besides exercising a good effect on the members, often do work of sterling value.—(Nature.)

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

In our light soil scarcely any of the members of the Brassica family succeed well, but we usually have excellent spring Cabbages, and Brussels Sprouts do us good service all through the winter months. The best way of obtaining a continuous supply of sprouts is to clear off all leaves that become yellow during the winter months, and also allow the top to remain. If the sprouts are required early, then it is best to cut the top off, which throws all the strength into the side sprouts. A good supply of this excellent vegetable is very serviceable, especially when Broccoli cannot be had. Broccoli comes in very useful in the spring, and they do tolerably well when good-sized plants are planted about the end of July. If planted earlier than this they will frequently club, and the large fine-looking plants will fall over in the winter and be spoiled.

Owing to the scarcity of Apples it will be necessary to make the most of Rhubarb. Some roots of this, as well as of Seakale, will be placed in the earliest vinery to force. Our system of management with small quantities has been frequently described. It is to lift the roots of the Seakale from the whole quarter, selecting the largest and most likely roots for forcing, and either planting out those not adapted for this purpose at once, or laying them in in a space of ground until it is convenient to plant them out in their proper position in the spring. We shall lift a quantity of Asparagus roots, and force them in a dung frame. They can be packed very closely together over the surface of the bed, but there must be a sufficient depth of soil under the roots to prevent their being burned with the heat of the manure. In the matter of forcing vegetables, of course much depends upon the time they are wanted. In small establishments a constant supply of Asparagus cannot be kept up from now until green Peas are ready, and it would be best for employers to arrange with their gardeners as to the time forced vegetables would be most acceptable. The late Mr. Robert Fish used frequently to make allusion to this matter, and it is one of considerable importance. Ladies and gentlemen know months before the time when they will be at home to receive visitors; but if they do not acquaint their gardeners of this in due time, they cannot expect to have proper provision made for the occasion.

We sowed a row of the new vegetable Witloof in June, the time stated upon the packet of seeds, but the leaves are still quite green; however, we shall lift a portion of the roots, cut the leaves off them, and store in a cool shed to be ready for forcing. The roots will be potted and forced in a dark place, and the growth will be cut when about 6 or 9 inches in length. A good supply of Mustard and Cress can be kept up by sowing the seeds in boxes and placing these in any house where there is a little heat.

### VINERIES.

The Vines in the earliest house have been started by giving the borders outside and inside the house a good supply of tepid water. The outside borders of all the early houses are annually covered with fermenting material as soon as forcing begins; this retains the heat in the border, which is raised a little by the tepid water; and although but little heat can be forced into the border by the heat of the material, still it must warm it to the depth of a few inches. In many instances when manure and leaves have been placed over the surface of the border they are left to the effects of cold rain, melted snow, and intense frost. This is often a very great mistake; the rain ought to be thrown off by wooden or other shutters, and these ought to be arranged so that the rain drains quite off the border, for it cannot but be injurious to conduct the rain water to the front of the border where the most useful roots are, and allow it to soak down there and destroy them. Sometimes the inside borders are covered with some heating material. This causes a little extra trouble in turning it over and adding to it to retain the heat, but it is the best treatment for the Vines, and also saves a considerable sum in fuel; and another item on the saving side is that not so much use is required for the syringe. The genial moisture from the manure, or, what is better, oak leaves and manure in about equal proportions, dispenses with syringing; still, on the forenoon of any sunny day it is as well to dew the canes over with tepid water.

As opportunity offers other vineries may be prepared for forcing by thoroughly cleaning the glass and woodwork, as well as washing the canes with soapy water after they have been pruned, and painting over the rods with the usual mixtures. Where Grapes are hanging it is still necessary to be very prompt

in removing all decaying leaves and berries. When the leaves are removed one principal cause of decay goes with them, as light and air are then much more freely circulated through the house.

### CUCUMBER HOUSE.

This demands daily attention to keep up the requisite degree of heat by night and by day, and to admit of a change of air by opening the ventilators a little about the middle of the day on every favourable opportunity. The shoots must not be trained in too closely to each other, as every leaf ought to be freely exposed to the light, and be close to the glass without coming into contact with it. There is so much condensed moisture continually running down the inside of the glass, and most on frosty nights, that any leaves in contact with it are speedily destroyed. Much good results from adding a very little surface-dressing to the border at intervals through the winter, which entices the roots to the surface, and causes the leaves to become of a deeper green than they would be without it. We are cutting excellent examples of Tender-and-True, Kelway's Conqueror, and another sort by the same raiser, the New Winter Cucumber.

### PLANT STOVE AND ORCHID HOUSES.

We are glad if any flowers at this period of the year to enliven the houses. Many species of the Orchid family do good service at this season, and now when their wants are better understood it is found that many which were formerly considered difficult subjects to deal with flourish well with the treatment given to ordinary stove plants. No Orchids are more useful or more easily managed than *Dendrobium nobile*; a plant of it at Loxford cannot now have less than five hundred fully expanded flowers upon it. They last in perfection for three weeks in a temperature at night of 55°. The *Calanthes* are in full beauty, and they may be said to be amongst the easiest cultivated of Orchids; from three to six strong spikes are produced from three bulbs in a 6-inch pot. Some persons grow a score or two of bulbs in a large pan, but the smaller number in 5 or 6-inch pots work-in better with the ordinary occupants of the stove. The pots require to be concealed by the foliage of other plants. *Calanthe Veitchii* throws up magnificent spikes, and the darkest-coloured varieties of it are truly grand. Some varieties are very pale, and the amateur who has a particular taste to gratify ought to see his plant in flower before purchasing it, as the colours of the flowers range from pale pink to reddish crimson.

Passing from Orchids the *Eucharis amazonica* is now becoming a common flower, but it will always be valuable for cutting for any purpose for which choice white flowers are required. It is of easy culture, but requires a temperature of 65° to bring it to perfection. The two best *Bouvardias* are *B. Vreelandii* and *B. Hogarth*; *B. jasminiflora* and others of that type are very beautiful, and some of them are of the purest white, but they are not well adapted for cutting.

### FLOWER GARDEN.

Now that the leaves have fallen from the trees it is desirable to have them cleared from the shrubberies and flower garden. The lawn should be swept clean, and everything made neat and enjoyable. The surface soil of the beds of spring plants should be stirred in fine weather, and weeds as well as withered leaves should be removed. The soil also requires to be pressed round the stems of some plants, as frost after rain is apt to throw them out of the ground. Pinks suffer most from this cause, but the ardent amateur will be constantly looking over his choice plants and will notice at once if anything is wrong. The leather-coated grub is a dangerous enemy to choice Pinks. We had about half a dozen of the grubs in our bed this year, and they did some damage before they were noticed. The grub eats the centre leaves first, then down to the heart of the plant, and when a plant is observed eaten in this manner the grub will in all probability be found buried in the ground to the depth of an inch or more close to the plant. It may be found just below the surface by scratching carefully with the fingers.

Carnations and Picotees are now safe in frames, and the pots plunged in cocoa-nut fibre refuse for the winter. Owing to the mild weather in October the plants have grown rather too much, but every means have been used to prevent their further growth; the lights are removed except during frost or wet weather. If the leaves become wet with rain at this season they are liable to spot, and the plants suffer more from this cause than from any amount of frost.

Auriculas are now parting with their superfluous leaves, and if they are not removed every few days they cause mould to settle around the necks of the plants; this mould if not removed before it penetrates under the outer covering of the stems destroys the plants altogether. It is of the utmost importance to destroy green fly on Carnations, Picotees, and Auriculas.—J. DOUGLAS.

## TRADE CATALOGUES RECEIVED.

James Dickson & Sons, Newton Nurseries, Chester.—Catalogue of Forest Trees, Shrubs, Evergreens, &c.

Francis & Arthur Dickson & Sons, "Upton" Nurseries, Chester.—*Catalogue of Forest and Ornamental Trees, &c.*  
Robertson & Galloway, 157, Ingram Street, Glasgow.—*Catalogue of Choice Gladioli, and List of Roses.*

## HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

NEWCASTLE-UPON-TYNE. March 21st and 22nd, 1877. Messrs. J. H. French, Benwell House, and J. Taylor, Rye Hill, Hon. Secs.  
ISLE OF THANET. August 30th. Mr. C. D. Smith, Hon. Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*Lady C.*).—Robinson's "Alpine Flowers for English Gardens."

PRIMULAS (*Mrs. Gillum*).—Apply to any of the florists who advertise in our columns. Amateurs do not like being troubled.

LEMON TREE UNHEALTHY (*H. F. G.*).—What you call scabs are scale insects (*Coccus hesperidum*). Treat them as directed in our number 816.

DENDROBIUMS (*R. S.*).—D. Falconeri, D. Parishii, D. speciosum, and D. Wardianum are evergreen or very nearly so; the difference between evergreen and deciduous depending in a measure upon the ripening of the growths.

HORTICULTURAL DIRECTORY (*Idem*).—Corrections should be made at office to the Editor at this office, which has been repeatedly announced in our advertising columns. No authority beyond that of a gardener is necessary.

FORCING LILY OF THE VALLEY (*E. D. Lyon*).—If you require Lilies of the Valley early, the crowns are best forced in bottom heat. A bed of leaves about 3 feet high is usually required, and in this the pots are placed, covering with about 6 inches of dry loose leaves. It is much better if a frame and lights be placed upon the leaves, which throw off rains and maintain a more equable temperature; besides, it may be necessary in severe weather to line the sides of the frame and bed should the heat decline, which ought not to be less than 75°, nor exceed 90°. When the flowers have grown 4 to 6 inches above the pots, the covering should be removed, and the plants be placed in a light position in a stove, where they expand and attain colour. We have seen them successfully forced by placing a rough frame of boards around the pots, and over that some boards so as to form a cover, leaving 6 to 8 inches of space from the surface of the pots to the boards, covering with leaves or litter about a foot to 15 inches deep, removing the Lilies to a warm house when the flower spikes were 6 inches long.

EXHIBITING CHRYSANTHEMUMS (*Whitehaven*).—The blooms sent do not belong to the large-flowering section, and they are only admissible for exhibiting in the classes for Pompons. The Ixora sent did not arrive in a fresh state, but it appears to be I. Williamsii, one of the best of the Ixoras.

LAPAGERIA RUBRA (*Amateur*).—Lapageria rosea is a native of Chili. L. rubra being only a higher-coloured form of L. rosea, which originated in this country.

REPOTTING DIPLODENDRAS (*Idem*).—They require to be repotted annually, removing most of the soil from the roots—all that comes away freely without injuring them.

CHARCOAL AND SOOT FOR FLOWER BEDS (*Epsilon*).—Crushed charcoal is good for flower beds. You may apply it at the rate of a bushel to 30 square yards. Soot is a first-rate manure, and may be applied at the rate of one peck to 30 square yards. It is best applied in spring prior to planting, pointing it in lightly with a fork, or it may be applied as a top-dressing after planting.

STORING SALSIFY (*F. W. B.*).—We have this little-esteemed but very delicious vegetable up to June by taking it up now, cutting off the tops about half an inch above the crown and storing in moist sand in a cool shed. If you do not require it until April you may leave it in the ground until that time, but we think the quality of that stored is better than that left in the ground, especially for late use.

MAKING PUTTY (*W. Ruff*).—It is more economical to purchase than to make putty by hand. It is made by adding linseed oil to whiting in the proportion necessary to form it into a dough-like consistence, taking care to have the whole thoroughly kneaded, so as to be soft and pliant without sticking to the hand. You will require about 56 lbs. of putty, but the quantity will depend in a great measure upon the size of the squares of glass, and the rebate in the rafters and sashes for receiving it.

HOTBED OVER FLUE (*Idem*).—You will need to place some rubble upon the flue, rather rough at bottom and finer upwards, the depth of rubble being about 9 inches, and upon this you will need about 6 inches of plunging material, as cocoa refuse, and another 6 or 8 inches' space for the cuttings.

RIVE D'OR ROSE (*Rus in Urbe*).—We fear the situation under the verandah will be too dark and dry; but as you say the plant is very healthy we should give it another chance, not pruning, but merely thinning out the shoots if too crowded, training them in their full length. The strong current year's shoots of this Rose do not usually produce flowers, however, until the second year. The Euonymus, of which you sent a leaf, is, we think E. fimbriatus.

CULTURE OF MINULUSES (*A Reader*).—We presume you intend to grow them in a greenhouse. We also presume that you have plants—seedlings or

cuttings, which should be kept over the winter in a cool airy part of the greenhouse, keeping them moist. Early in March they should have 7-inch pots, well drained, for though the Mimulus delights in moisture it does not thrive when the soil is soddened and sour. Cuttings may be taken in March, which strike readily in gentle heat, keeping moist and shading from sun until rooted. They should be put into small pots at first, and shifted into larger as they advance, giving the blooming pots in May. In June and onwards they will flower finely. They require a position near the glass and abundant supplies of water, never allowing the leaves to flag, and when in flower the plants should be shaded from hot sun. A compost of one half of turfy loam, and the other half formed of equal parts leaf soil and dry cow dung, the whole well mixed together, is suitable.

POTTING ACHIMENES (*Idem*).—The tubers may be started at any time from February up to June. They require a compost of equal parts of peat, leaf soil, and turfy loam, and a temperature of 65° to 75°. The plants will appear in about ten days or less if the soil is kept moist.

SOWING SEEDS (*Idem*).—Seeds of Carnations, Centaurea candidissima, Echeverias, Fuchsias, Pelargoniums, Acacias, and Cannas may be sown any time after the middle of February in a hotbed.

BEGONIAS AND GLOXINIAS (*Idem*).—They will succeed in a temperature of 45° to 55°, but will require to be started in heat in spring. A few of the best Begonias are Chelsoni, Model, Vesuvius, Stella, Sedeni, Acme, Boliviensis, and Pearcei of the tuberous section; and insignis, Saundersiana, Weltoniensis, and parviflora of the herbaceous class. Gloxinias.—Erect flowers: Duchess of Edinburgh, Sir Stafford Northcote, Benjamin Disraeli, Fanny Wilder, Purple Prince, Sunshine, Grand Monarch, Madame Courant, John Gray, Brilliant, National, and Triomphe des Gloxinias. Drooping flowers.—The Sultan, Duchess of Teck, Gamos, Sir John Lubbock, Miss H. de Rothschild, Patrie, Lord Derby, Alsace, Madame Patti, Etna, Madame de Smet, and Hon. Mrs. Yorke.

DRAINING SMALL GARDEN (*Delta*).—It is quite as important to drain a small garden as a large field, but whether it be necessary to do so depends upon the presence of water lodging in the subsoil or not. If the garden be wet we should have a drain up the centre of 3-inch drain tiles laid 8 feet 6 inches or 4 feet deep, and having a proper fall and outlet. If you drain crosswise the drains must not be more than 18 feet apart.

CANTERBURY BELLS (*N. C.*).—Plant them out at once in light moderately rich soil in an open situation, but sheltered. The plants being small we should not allow them more than 6 inches' distance apart every way, otherwise they require a foot distance apart. They grow from 15 to 24 inches high, and flower from May to July.

SELECT VIOLETS (*Weston*).—The six best Violets are—singles: Victoria Regina, White Czar, and Devonians. Doubles: Neapolitan, Odorata pendula (New York variety of Neapolitan), Marie Louise, and Queen of Violets. If only six are wanted omit the Neapolitan. Prince Consort is the finest of all single Violets, but it is not yet in commerce.

CHRYSANTHEMUMS (*W. B. H.*).—Chrysanthemums are included in our pamphlet on "Florists' Flowers," post free 4d. Detailed cultural notes from successful growers will shortly appear in our columns.

FUNGUS IN VINE BORDER (*Subscriber*).—We presume that the fungus is to be found in the border in patches. In that case the most effectual remedy is to remove all the soil containing the spawn, and dust quicklime thickly over the space from which it has been removed, replacing with fresh soil.

MANAGEMENT OF POT VINES (*A Constant Reader*).—Vines which have been cropped heavily do not succeed well the following season. It would not be safe to shake the soil from the roots to repot them. We advise you to surface-dress with rich soil those in 16-inch pots, and repot the two in 8-inch pots, without disturbing the roots much, into 11-inch pots.

PLANTS FOR AQUARIUM (*Idem*).—Equisetum flaviatile, Aponogeton distachyon; Nymphaea nitida, minor, and odorata; Potamogeton nutans, Nuphar pumila, Stratiotes aloides, Menyanthes trifoliata, Richardia thiopica, and Myriophyllum spicatum.

DWARF PLUM TREES BARREN (*Ignoramus*).—You do not say whether your trees produce blossoms. If they do, it would seem that the varieties are too tender to withstand the effects of the spring frosts. Reine Claude de Bay and Prince Englebert are the only sorts in your list which we have tried as pyramids. We never could induce them to bear when they were removed biennially. We advise you to leave off lifting the trees. The sorts we grow as pyramids are mostly kitchen Plums, and they bear enormously—namely, Mitchelson's, Prince of Wales, Victoria, Pond's Seedling, Diamond, Orleans, Goliath, Rivers' Prolific, and Prince Englebert. All the finer sorts are grown on walls or in the orchard house. You will find all the necessary instructions for the culture of bush and pyramid trees in "Doings of the Week."

TREATMENT OF DENDROBIUMS (*Ashbury*).—Remove the pseudobulbs that form on the old growths as soon as a few roots are formed at their bases. The best time to repot Orchids is when they begin to make roots. "The Orchid-Grower's Manual" will answer your purpose, price 2s. 7½d. post free from our office.

WINTERING CACTUS (*Lady Subscriber*).—They would do in your granary with zonal Pelargoniums. The Cactuses would not require any water during the winter months, and frost must be kept from the plants.

POTTING LILIUM AURATUM (*Idem*).—You must not remove any live roots from the base of the bulbs, but remove the flower stalks with all the roots attached to them. It is quite time the bulbs were repotted.

MARÉCHAL NEIL ROSE UNHEALTHY (*J. A. P.*).—We fail to observe any disease on the leaves sent. They are probably dying off in the ordinary course of nature at this season. If the roots are healthy we think the plant will start well next year.

TEMPERATURE OF INTERMEDIATE HOUSE (*S. H. C.*).—During winter from 50° to 55°, it may even fall below 50° in cold weather. In summer no artificial heat is needed, and the temperature will rise according to the weather.

CARBOLIC DRESSING FOR PEAS.—Mr. Douglas, in reply to Mr. R. Foster says that this dressing does prevent mice from eating the Peas after they are sown. It is termed "King's Patent Carbolic Dressing," and should be advertised. We intend to try it on the seed Wheat, to prevent the attacks of rooks.

COVERING VINE BORDER (*J. T. T.*).—You would not err in covering the border as you propose, but in the absence of data as to condition of the border and Vines, and as to the time that Grapes are required, we are unable to give you definite advice as to the best mode of procedure.

**KITCHEN APPLES (L. T. K.).**—It is always advisable to note the sorts which flourish and yield best in a given district, for Apples seem to have local proclivities; for instance, in some districts the Hawthornden will not thrive, while in others it is one of the most profitable. Keswick Codlin is one of the most productive of culinary Apples. Beauty of Kent is valuable, as also are Dumelow's Seedling and the Gooseberry Apple. Blenheim Pippin forms a fine orchard tree, but is somewhat slow in arriving at a free bearing state. You may plant any or all of these named as standards.

**LILIES (Brixton).**—The arrangement has not been published.

**MUSCAT VINE IN STOVE (Y. L. B.).**—It would succeed, the cane being trained 15 to 16 inches from the glass. From January to March would be a good time to introduce the Vine. Venn's Black Muscat and Muscat of Alexandria are suitable, the latter being the finest of all Grapes. Any time from November to March in dry weather is a proper time to enlarge a Vine border, but November and March are preferable periods.

**WIRING CAMELLIA BLOOMS (Idem).**—You will need fine bouquet "stem" wire, which may be had of most florists, &c. The wire is carefully pushed through the flower under the petals about half an inch above its base, and another wire is pushed through on the opposite side, and both so as to have equal lengths of wire projecting on each side of the flower, forming a cross. The wires are then brought together downward, and a spray or two of Adiantum is placed around the flower, the wires are twisted, grasping the stems of the Adiantum, and form an artificial stem. The flowers require to be carefully handled, for if bruised they will in a short time become discoloured. Except for placing in water when it is necessary to have natural stems, we do all ours in the above way, and so preserve the wood (that would otherwise be removed) for future growth.

**APPLYING LIQUID MANURE (William J. Jervis).**—Weak liquid manure applied to Rose trees, Sweet Williams, and Stocks, also Cabbages and Greens of all kinds when the ground is saturated with moisture, is calculated to make the soil too wet, sodden and sour.

**SALSAFY (Idem).**—You are under a mistake as to the use of Salsafy. It is the roots that are edible, and not the tops or sprouts. The roots should be freed from fibres, washed clean, and boiled until tender, then have the outer skin peeled off, serving with melted butter.

**LATE PLUM (Idem).**—The Plum you describe is a kind of Bullace, we think the Royal Bullace, valuable for its lateness. There are other late culinary Plums very much better, as Coc's Late Red and Wyedale, a late form of Winesour, and grown extensively in the north.

**GRUBS (C. S. Bath).**—They are not the Phylloxera, but the larvae of some Saw-fly. A little gas lime mixed with the soil is the best remedy.

**VIOLETS (M. Hamilton).**—The leaves indicate excess of warmth and deficient light and ventilation. They are weak and spindly.

**KELP AS MANURE (E. L. Whitty).**—It is an excellent manure for Asparagus, Seakale, and Beet. Kelp is only burnt seaweed, and we always applied this unburned.

**GAS-HEATING (E. B.).**—In our number 341 are drawings and directions relative to various stoves.

**GLAZING.**—If "D. P. B." will send his name and address to Mr. Thomas Hardcastle, valuer, Boroughbridge, Yorks, he can be furnished with particulars from practical experience of glazing with lapless squares and no putty.

**SILK COCOON LIQUOR (D. P. Bell).**—If it has the beneficial properties you mention, the manufacturers should advertise it.

**NAME OF GRASS (W. W. E. W.).**—It is the Soft brown Sedge, or *Carex intermedia*, and is, as you say, very ornamental on the margin of water.

**NAMES OF PLANTS (Iris).**—No one can name Conifers from sprigs; cones should accompany the leaves. (W. F.).—Florists' varieties, and from mere leaves, we cannot name plants.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LES BASSES-COURS D'ANGLETERRE.

#### CHAPTER XI.—FALKONERS, EDENBRIDGE.

We knew, of course, that Mrs. Christy was a most enthusiastic fancier, and has spared no sum to procure a yard of Buff Cochins as good as possible, but we were not prepared for any building so elaborate as we found upon her premises. We can only say, that all other establishments which we have had the pleasure of seeing are mere trifles to this in minute and elaborate arrangements. It is not a large place, but at every step we took we saw something new and out-of-the-way. At the back of the house are an orchard and a paddock enclosed with wire fencing, and on the left-hand side is a long row of houses with grass runs in front of them; beyond this are some portable houses in enclosed yards, and then further on still are some good open fields. It was, however, with the range of houses that we were so taken, for nothing possibly could be more perfect or more suitable for prize birds. We will endeavour to describe them.

They are a long range of red brick houses under one roof. At the back of them there is a passage from which every bird in each run can be inspected, and in front of each house is a gravel and a grass run, from which a door can be opened at pleasure to let the inmates walk into the orchard or paddock beyond. This may seem all commonplace enough, and to much resemble many yards formed on the same principle; but it was the unique arrangement, the wonderful brightness of everything, and the perfect cleanliness which made the houses so very noticeable. The first partition in the long range of buildings was the poultry room, where were staged on shelves a set of japanned canisters, on which were painted the names of the various contents—hemp seed, grits, spica, Dear's food, roup pills, condition powders, and many more such condiments; below them were the corn bins, in

which we found every conceivable variety of grain, dari, buck-wheat, &c. On the floor were rugs and mats, and there were two chairs and tables, so that Mrs. Christy could have a "kettledrum" there on any winter afternoon as well as she could in her own boudoir. In the passage behind the pens we saw stores with polished fireirons, and the grates blacklead to a perfect pitch. This corridor was lit with gas-burners, which had cut-glass globes. The pens were littered with clean wheaten straw, and had the names of their inmates painted on plates over the top like we should expect to find in model stables. The feeding pans and drinking vessels were as clean as new, and the grass outside closely mown and planted with ornamental shrubs. This is but a faint description of the wonderful order and cleanliness we found, and we have only to add that neither Mrs. Christy nor her poultry-man had the smallest idea we were in the neighbourhood, so the place had not been furnished and polished up unnaturally for the sake of the "Basse-Cour."

Now a few words as to the inmates. Buff Cochins everywhere—in the runs, orchard, paddock; flocks of pullets, droves of cockerels, hens, adult cocks, and cockerels penned in numbers of four or five. When we passed from the garden door and first saw the pullets basking in the sun they looked like a long buff bank of flowers. We could hardly realise they were a mass of Cochins, but so they were, and a good lot too; of course some were a little ticked in neck hackle or black in tail, but those were being rapidly sent to the higglers at 3s. or 4s. each, and only the *elites* would soon remain. The cockerels seemed many of them more backward, but we saw some good birds, and are pleased to have seen them since in the prize lists. Of the old hens one we were quite taken with, immense and well feathered, a "Tomlinson" we were told; if she only gets over the moult well she will be very valuable. And then among the adult cocks we saw "Kaiser II." son of Mr. W. A. Burnell's champion; and there was too "Canterbury" which we believe we saw second at the Palace among the old Buff cocks, a little hocked he was, but so honestly shown; and then there were in those polished wood loose boxes other celebrities and other cockerels of 1875, which only wanted a few weeks more to get them over the moult. We were much struck by everything, and congratulate Mrs. Christy on her manager who, single-handed, does everything down to keeping the turf edgings trim, and picking off the buds of the "golden feather," which edged the path to the poultry-room door.

We saw, too, some good Sultans and a Cuckoo Sultan, which is a bird we had never seen before, bred too as it was from the Whites; but these are only looked upon as playthings and not as the real fancy. We could but think it a pity that Mrs. Christy did not keep another breed, she has such ample space, and the shade is so adapted for light or white-coloured birds. We hardly think that so far Mrs. Christy has had the success her birds deserve, but she has now thoroughly mastered the subject, and we would as soon allow her to select Buff Cochins for us as any other fancier; so those who are foolish enough to try and palm off bad stock upon her will find themselves worsted, but her birds are now so good and numerous that we should imagine that she will not need fresh blood for a long time to come.

Falkoners is about a mile from Edenbridge station on the South-Eastern Railway, and those who want to see a model establishment perfect in itself and scientifically managed cannot do better than obtain permission from Mrs. Christy to see her yards and runs, for they are places to be remembered and even to be marvelled at.—W.

A MEETING OF THE POULTRY AND PIGEON FANCIERS OF NORTH-UMBERLAND AND DURHAM will be held on Friday, December 1st, at two o'clock P.M., in the Cloak room, Town Hall, Newcastle-on-Tyne (entrance the door below the show), to form an Association for the furtherance of their mutual interests.

### THE BIRMINGHAM CATTLE AND POULTRY SHOW.

We have great pleasure in stating that the Exhibition of fat cattle, sheep, pigs, roots, corn, and poultry in Bingley Hall on the 13th, 14th, 15th, 16th, and 18th of December next, will be by far the largest ever held in that building. The principal increase will be in cattle, poultry, and Pigeons, and this must be very gratifying to the Council, as it shows they were guided by a wise policy in the changes which were made in the regulations for the current year. We refer especially to the fixing of the Show later than that of the Smithfield Club, and receiving stock which had been exhibited there; and also to the alterations in the poultry and Pigeon department, whereby non-members can exhibit upon payment of 8s. per pen. So far the innovations have been crowned with complete success, but it remains to be seen whether the days fixed upon will be as advantageous as those of former years. The ingenuity of the Council and the Secretary (Mr. J. B. Lythall) have been taxed to the utmost to find accommodation for the large increase in the entries, and

the space usually allotted to the implement department has been materially encroached upon. Many of the schedules of implement exhibitors have had to be returned to them, and the others have been confined to the smallest possible space. The following is the number of entries for the present year, together with a comparative statement of the four previous years:—

	1872.	1873.	1874.	1875.	1876.
Cattle.....	133	135	152	119	204
Sheep.....	96	89	69	72	105
Pigs.....	63	60	59	41	66
Corn.....	53	27	48	22	231
Roots.....	131	273	167	182	231
Poultry.....	1,996	1,850	2,102	1,950	2,032
Pigeons.....	881	491	975	541	669
Total.....	2,911	2,925	2,972	2,927	3,297

—(Midland Counties Herald.)

### SWINDON POULTRY SHOW.

THIS Exhibition has wonderfully increased in size and quality, and we can well believe that its able and energetic Committee have it in their power to make a great county show. The Show on November 24th and 25th was prettily arranged, and the Exhibition Hall was well lighted and lofty. The Secretary was unable to attend on the first day from a family bereavement, but he left an excellent substitute in his successor.

**Dorkings**, Coloured, were wonderfully good, the first Peterborough cock with a fine hen winning first and the second champion cup. Second and third also were good birds, the cockerel in the latter being excellent in shape. 8 (Salter) a very promising pair of chickens. Buff *Cochins* were of much merit, and the first-and-cup hen were very superior. The second-prize pen contained a good cockerel. In the next class old Partridges won first, the hen very good; capital Whites second, and Whites again third, an adult hen and a cockerel. In Dark *Brahmas* we much admired the first hen, she was good all round; while second went to good birds too, the hen prettily marked and well feathered. Lights were good, chickens of fine quality being first. The *Minorcas* we did not think so much of. Whites won first. *Spanish* were a fair lot, a cockerel with a good face and comb being first with a very neat pullet. The *Polands* were very good, and by the instrumentality of Mr. Burrell two classes had been given them. They mustered a score of pens, in which all colours were represented. Golds were first and Blacks second in both classes, while the thirds went in adults to Blacks and in chickens to Golds. 80 (Hinton), very good Silvers, and 81 (Silvester), excellent Golds. 96 (Burrell), good Black chickens. *Houdans* were very good, the first well marked and large. 109 (Pearce), good birds, especially in combs, but not crested enough. A dozen pens of *Creves* put in an appearance. A large pen of adults won first-and-cup. In the second pen we greatly admired the shape of the hen. *Game* were fair classes, the quantity exceeding quality. The first Brown Red cock had good carriage and was in fair colour. Second also a smart cockerel and pullet. In the next class Duckwings won first, the hen good in colour and showy. *Hamburgs* made very fair classes. We thought the Golden-spangled and the Golden-pencilled the best. The latter class was particularly good in its winners. *Leghorns* did not muster very strongly, but the three prize pens of Browns were very good, and we noticed a general improvement in ears and carriage of tails. White *Leghorns* were not very grand. It seems difficult to get colour in body feather and ears at the same time. *Game Bantams* mustered thirty-five pens, but the winners only need comment. The first pen of Black Reds were very smart. In the Variety Bantam class Silver-laced were first, and Blacks second and third. Mrs. Crook had a fair pen of White-booted, but out of condition rather. The Variety class contained six pens, where Malays won the prizes; all of good quality and feather. 257 (Burd) were entered as "Longshins," but they would have well passed for fair Black *Cochins*.

The *Aylesbury Ducks* and *Rouens* were both excellent, the latter, perhaps, more especially. In the Variety Duck class very good East Indians won first—in fact, as good a pen as we have seen for a long time. *Geese* and *Turkeys* both came well to the front. We noticed a very good pen of Whites of the latter breed in pen 425 (Surmon).

*Pigeons* were very excellent, and Mr. Jones made a good selection for his awards. He gave the cup for best pen to Mr. Baker's Carrier cock, and the cup for second best to Mr. Salter's beautiful Silver English Owl. The *Fantails* were good, and so were the *Turbits*; in the latter class a bird of deep black colour won. *Dragoons* made two strong classes—namely, twenty-five Blue or Silvers, and thirty of any other variety. Mr. Woods sent his cargo from Mansfield and secured many prizes, but Mr. Lush had his White in a good third in its class. *Maggies* were a pleasing class between the two Oxford fanciers, and the "Egrov" one came off the best, the prizes going to a Black, a Yellow, and a red, all in good feather and condition. *Jacobins* made a large class of good quality, but the prizes went to Mr.

Baker, and others had only to be "highly condemned," but among them Mr. Maynard's Red was a beautiful bird, good in colour and chain. In the Variety class a capital Trumpeter of the so-called new type won first. Mr. P. H. Jones judged the *Pigeons*, while Mr. John Martin awarded the poultry prizes, giving much satisfaction to all present, and using that precision which so marks his awards. We give the prize list below.

**POULTRY**.—**DORKINGS**.—1, A. Darby. 2, Mrs. Allsopp. 3, W. Wallis, jun. **COCHINS**.—Buff or Cinnamon.—1, H. Tomlinson. 2, A. Darby. 3, Mrs. Allsopp. *who*. Mrs. A. Tindall. Any other variety.—1 and 2, Mrs. A. Tindall. 3, Rev. R. S. Woodgate. **BRAHMAS**.—Dark.—1, Newnham & Manby. 2, E. Pritchard. 3, Morris & Cameron. *Cottagers*.—2, E. Watts. *Light*.—1, T. A. Dean. 2, Mrs. A. Tindall. 3, A. Iva. *Cottagers*.—1, W. Chivers. 2 and 3, J. Lee. **MINORCAS**.—1, H. Elston. 2 and 3, J. G. Rowe. **SPANISH**.—1, J. W. Fielden. 2, Mrs. Allsopp. 3, J. Baker. *Cottagers*.—1, T. Osman. 2 and 3, H. Wallis. **POLANDS**.—1, E. Burrell. 2, A. Darby. 3, T. Norwood. *who*. J. Hinton. A. & W. H. Silvester. *Chickens*.—1, A. & W. H. Silvester. 2, T. Norwood. 3 and *who*. E. Burrell. **HOUDANS**.—1, Mrs. F. St. John. 2, S. W. Thomas. 3, E. J. Blair. *Cottagers*.—1 and 2, J. Watts. **CREVE-CEURES**.—1 and Cup. S. A. Vickery. 2 and 3, F. Burrell. *who*. M. H. Sturt. *Cottagers*.—1, F. W. Wilkins. 2, J. T. Jarman. **GAME**.—Black breasted Red.—1, Rev. A. Cruwys. 2, F. Warde. 3, E. Woodford. *Cottagers*.—1 and 2, J. T. Mew. *Brown-breasted Red*.—1 and 2, F. Warde. 3, R. Swift. Any other variety.—1, J. T. Browne. 2, A. Stradling. 3, E. Winwood. **HAMBURGERS**.—Golden-spangled.—1, C. May. 2, J. Calcutt. 3, T. Pope. *Cottagers*.—1, A. Simpson. *Silver-spangled*.—1, T. Pope. 2, F. Edwards. 3, T. Patterson. *Cottagers*.—1, T. Patterson. 2, J. Taylor. *Golden-pencilled*.—1, T. K. Castell. 2, A. Livings. 3, O. E. Cresswell. *Cottagers*.—3, T. Pope. *Silver-pencilled*.—1, D. E. Snell. 2, J. Orledge. 3, E. Wagh. Any other variety.—1, G. H. Massey. 2, J. W. Kelleway. 3, Stott & Booth. *Cottagers*.—1, W. Chapman. 2, T. B. Watson. **LEGHORNS**.—Brown.—1, F. L. Green. 2 and 3, A. Kitchen. *White*.—1, E. C. Seaman. 2, Mrs. W. P. Hughes. 3, E. Dell. **BANTAMS**.—Game.—1, W. Adams. 2, R. Swift. 3, E. Winwood. *Cottagers*.—1, J. Forward. 2, J. Merrett. Any other variety.—1, G. Holloway, jun. 2, K. H. Ashton. 3, F. C. Davis. Any OTHER DISTINCT VARIETY.—1, R. Moore. 2, J. Hinton. **SELLING CLASSES**.—*Cocks*.—Price not to exceed £1 10s.—1, Miss J. Milward. 2, Morris and Cameron. 3, F. Glanville. *Cottagers*.—1, J. Glanville. 2, J. K. Castell. Price not to exceed £2.—1, F. Glanville. 2, W. E. Smith. 3, H. Haddrell. *Cottagers*.—1, A. Shepherd. 2, T. Latter. *Cocks*.—Price not to exceed £3.—1, W. E. Smith. 2, S. Walton. 3, J. Hinton. *Hens*.—Price not to exceed £4.—1, Mrs. Allsopp. 2, Capt. F. G. Coleridge. 3, Miss J. Milward. *Cottagers*.—1, 2, and 3, J. Lee. **DUCKS**.—*Aylesbury*.—1, Mrs. A. Tindall. 2, Dr. E. Snell. 3, S. R. Harris. *Cottagers*.—3, J. Rees. *Rouen*.—1, Dr. E. Snell. 2, S. Salter. 3, Dr. E. Snell. *who*. J. B. Baily. *Cottagers*.—3, T. Osman. Any other variety.—1, G. S. Sainsbury. 2, J. A. & J. H. Silvester. *Cottagers*.—1, H. Haddrell. 2, J. Shadleton. 2, Mrs. H. J. Bailey. 3, Dr. E. Snell. *Cottagers*.—1, W. Smith. **TURKEYS**.—1, Mrs. H. J. Bailey. 2, F. Warde. 3, Rev. E. Withington. **PIGEONS**.—**CARRIERS**.—*Cock*.—1 and 2, J. Baker. 3, S. Harding. *who*. H. M. Maynard. *Cottagers*.—1, A. Simpson. 2, F. Rosier. 3, E. Jones. *Hen*.—1 and 2, E. Burton. 3, H. M. Maynard. *Cottagers*.—1, F. S. Dean. 2, E. Jones. 3, A. Simpson. **TUMBLERS**.—*Short-faced*.—1, 2, and 3, J. Baker. *Cottagers*.—2, C. Sainsbury. Any other variety.—1, J. Baker. 2, C. Sainsbury. 3, J. Baker. *Cottagers*.—1, J. Wood. 2 and 3, T. B. Watson. **POULTRY**.—1, 2, and 3, J. Baker. *who*. A. P. Byford. **DRAGONS**.—*Blue or Silver*.—1, W. G. Flanagan. 2 and 3, R. Woods. *Cottagers*.—1, W. Phillips. 2, W. Affleck. 3, F. S. Dean. Any other variety.—1 and 2, R. Woods. 3, J. Lush, jun. *Cottagers*.—1 and 3, E. Sadler. 2, J. Ireland. **OWLS**.—*English*.—1 and 2, S. Salter. 3, J. Salter. *who*. J. Barnes. *Foreign*.—1, J. J. Sparrow. 2 and 3, J. Baker. *who*. T. Chambers. **TURBITS**.—1 and 2, S. Salter. 3, G. W. Webster. *Cottagers*.—1, 2, and 3, A. Simpson. **BARBS**.—1, G. W. Webster. 2 and 3, H. M. Maynard. *who*. J. Baker. *Jacobins*.—1, 2, and 3, J. Baker. **FANTAILS**.—1 and 2, H. M. Maynard. 3, J. F. Loversidge. *Maggies*.—1 and 2, S. Salter. 3, F. P. Bulley. *who*. F. P. Bulley. S. Salter. *Cottagers*.—2, E. Jones. **ANTWERPS**.—*Short-faced*.—1, J. Kendrick, jun. 2, G. Colson. 3, H. Yardley. *who*. J. Chandler. *Cottagers*.—1, J. E. Cottell. 2 and 3, W. Hopkins, jun. Any other variety.—1, S. Salter. 2, R. Frost, jun. 3, J. Watts. *Cottagers*.—1, F. Affleck. 2 and 3, W. Phillips. **HOMING**.—1 and 2, J. L. Burgess. 3, H. Stanhope. **LOCAL CLASSES**.—1 and 2, W. Phillips. ANY OTHER VARIETY.—1, J. Baker. 2, H. Yardley. 3, F. E. Bulley. *Cottagers*.—1 and 3, F. Saunders. 2, E. J. Cole. **SELLING CLASS—PAIRS**.—Price not to exceed £1 10s.—1, J. Baker. 2 and 3, S. Salter. *Cottagers*.—1, A. Simpson. 2, T. Patterson. 3, J. Wood. Price not to exceed £3.—1, C. Parson. 2, G. Packham. 3, E. Burton. *who*. H. S. Hansford. S. Salter. ANY VARIETY.—*Young Local Birds*.—1, J. Sykes. 2, F. Affleck. 3 and 4, A. Simpson. **CAGE BIRDS**.—**CANARIES**.—*Belgians*.—1 and Cup. Mrs. W. C. Drummond. 2, H. T. C. Sels. *who*. J. A. Sleep. 3, C. J. Salt. 3, C. J. Salt. *Yellow or Yellow-marked*.—1, J. A. Sleep. 2, Miss S. Northcott. 3, C. J. Salt. *Cottagers*.—1, Mrs. Phillips. 2, E. Atcherley. 3, T. F. Britain. **GOLDFINCH**.—1, G. Bown. 2, J. Daniels. 3, J. Hopkins. *Cottagers*.—1 and 3, S. Cox. ANY OTHER VARIETY.—1 and 3, Mrs. W. C. Drummond. 2, J. Johnson. *Cottagers*.—1, C. Hewitt. 2, E. Day. 3, W. Fisher. **WHEAT-EATERS**.—1, J. Cranmer. 2, A. Archer. 3, C. King. *who*. E. Pepper. *Cottagers*.—1, E. Britain. 2, J. Ireland. *who*. J. Ireland. 2, T. Latter. **HIA LAYAN**.—1, A. W. Whitehouse. 2 and 3, H. E. Gilbert. *Cottagers*.—1, J. Ireland. 2, Master H. Smith. 3, Master A. Hartley. **SILVER-GRAY**.—1, Hon. F. P. Bouvier. 2 and *who*. F. J. R. Nunn. 3, J. Gardner. ANY OTHER VARIETY.—1, Mrs. L. Ainsworth. 2, H. Suggett. 3, Miss E. Tateason. *who*. R. Bright. H. Batten. *Cottagers*.—1, W. Cox. 2, H. Batten. 3, C. Reynolds. **CATS**.—**TORTOISESHELL**.—1, Mrs. Scamman. 2, J. Duck. 3, Mrs. L. U. Gill. *who*. Master A. G. Jones. *Cottagers*.—1 and 2, Master A. G. Jones. 3, Miss A. Clegg. **TABBY**.—1, E. Baxter. 2, Mrs. Turner. 3, R. Kitchen. *who*. C. King. A. Phelps. *Cottagers*.—2, A. Simpson. 3, P. Hughes. **BLACK**.—1, C. King. 2, H. Chapman. 3, E. Bowker. **LONG-HAIRED**.—1 and Cup. T. Whiteman. 2, G. Owen. 3, Mrs. L. U. Gill. *who*. Mrs. H. Freke. Mrs. M. G. Sprague. 2, *Cottagers*.—1, J. C. Rogers. 2, Mrs. Trinder. 3, T. Morse. ANY OTHER VARIETY OR COLOUR.—1, J. Bott. 2, C. Chamber. 3, S. Hickman. *Cottagers*.—1, J. A. Stone. 2, W. Eatwell. 3, W. C. Pates.

### IPSWICH POULTRY AND PIGEON SHOW.

THIS was held on November 23rd in the Corn Exchange. The birds were exhibited in wooden pens belonging to the Society, which rather obstructed the light. Straw was used for the bottom of the pens, which in one or two instances hid the feet of a few duck-footed birds. The Judge was Mr. P. H. Jones of London.

**Dorkings** (Coloured), cocks.—First and second good birds. No. 4 we think should have had a notice. *Dorkings* (hens, any colour).—First, second, and third well placed. *Cochins* (Cinnamon or Buff), cocks.—First not, in our opinion, half as good as No. 29, which took second prize. *Cochins*, any other colour, properly placed. The first grand bird, extremely well feathered. *Cochins* (hens, any colour).—First and second good. *Brahmas* (cocks, Dark).—First (No. 61) a good-coloured bird, but comb

twisted and large. No. 63 we preferred to any in the class. Brahmas (Light). Cocks.—First, second, and third good birds, but we preferred No. 63 to the third. Brahmas (hens, any colour).—No. 82 (highly commended) we should have placed second if not first, but it is difficult to judge when Lights and Darks are mixed. *French*.—Classes well filled for a local show. No. 92 should have had a card. *Game* (cocks, any colour) a poor class. First not awarded; second a smart Duckwing. *Game* (hens, any colour).—First bad colour, and fantailed; third superior. *Hamburghs* (Gold or Silver-pencilled). Cocks.—First a smart bird, but black tail; second quite equal to first. No. 127 a good bird, and worthy of a card. *Hamburghs* (Gold or Silver-spangled). Cocks.—First good, second Silver, lobes discoloured. No. 137 a fair bird. *Hamburghs* (Black, cocks).—We should have placed the second first, and first second, the latter having a good comb, and being a much more stylish bird. *Hamburghs* (hens, any colour).—First a splendid bird in good condition, but we should have preferred the highly commended (No. 162) to either the second or third.

*Ducks and Drakes* Aylesbury or Rouen).—First a good pen. Selling class (cocks or drakes).—First a good bird; could have taken a prize in the open class. Selling class (hens or Ducks).—First only second-rate; second not worthy a card; third best in the class.

*Game Bantams* (cocks).—First a good Black Red; second good, but out of condition. *Bantams* (Black or White) a poor class. *Bantams* (hens, any variety).—First Silver Sebright; second Black Red, much better in the class; third Gold Sebright, bad tail. We would here mention the inconsistency of showing *Game Bantams* with Sebrights, &c.

The *Pigeons*, though not numerous, were pretty good; the winners, as a rule, very fair birds.

**POULTRY.—DORKINGS.**—Coloured.—Cocks.—1 and 2, Henry Lingwood. 3, J. Everett. Any colour.—Hens.—1, Rev. E. Bartrum. 2 and 3, Henry Lingwood. COCHINS.—Cinnamon or Buff.—Cocks.—1, W. Smart. 2, Lady Gwydyr. 3 and *vhc*, Henry Lingwood. Any other colour.—Cocks.—1 and 2, Lady Gwydyr. 3, G. B. C. Breeze. Any colour.—Hens.—1 and 2, Lady Gwydyr. 3, G. B. C. Breeze. **BRAHMAS.**—Dark.—Cocks.—1, G. S. Pearson. 2, Lady Gwydyr. 3, J. Levett. Light.—Cocks.—1, S. Reid. 2, Lady Gwydyr. 3, H. Mitchell. Any colour.—Hens.—1, G. B. C. Breeze. 2, G. S. Pearson. 3, G. Burrell. **FRENCH FOWLS.**—Cocks.—1, Dr. E. Waller. 2, M. H. Start. 3, E. Burrell. Hens.—1, A. W. Darley. 2, E. Burrell. 3, M. H. Start. **GAME.**—Cocks.—2, A. P. Byford. 3, A. W. Blood. Hens.—1 and 2, T. Doewra. 3, A. P. Byford. **HAMBURGHS.**—Gold or Silver-pencilled.—Cocks.—1, W. K. Tickner. 2, H. R. Platin. 3, T. Fenn. Gold or Silver-spangled.—Cocks.—1, W. K. Tickner. 2, H. R. Platin. 3, J. Everett. Black.—Cocks.—1, Nutman & Wright. 2, W. Clarke. 3, E. Elliott. Any colour.—Hens.—1, W. K. Tickner. 2, H. R. Platin. 3, W. Clarke. **DUCKS.**—Aylesbury or Rouen.—1, Mrs. C. Burners. 2 and 3, J. Everett. Any other variety.—1, Duchess of Hamilton. 2, T. Doewra. 3, W. R. Pratt. **SELLING CLASSES.**—Any variety except *Bantams*, *Cocks* or *Dyakes*.—1, S. Levett. 2, J. Everett. 3, Mrs. C. Burners. Hens or Ducks.—1, W. Clarke. 2, S. Felgate. 3, Lady Gwydyr. *Bantams*.—1, W. Holmes. 2, L. C. Morrell. 3, Mrs. J. Longe. *Bantams*.—Game.—Cocks.—1 and 3, W. Jay. 2, F. Bennett. 3, W. Jay. Black or White.—Cocks.—1, L. C. Morrell. 2, H. J. Ludlow. Any variety.—Hens.—1 and 3, W. Holmes. 2, W. Jay.

**PIGEONS.—CARRIERS.**—Single.—1 and 2, A. P. Byford. **BARBS.**—Single.—1, H. M. Maynard. 2, H. Yardley. *vhc*, A. P. Byford. **FANTAILS.**—Single.—1 and 2, J. F. Loveridge. **TAUPETERS.**—Single.—1, F. Joy. 2, W. V. Lodge. **DRAGONS.**—Single.—1 and 2, W. Smith. **ANTWERPS.**—Single.—1, H. W. Weaving. 2, S. Birchenall. **ANY OTHER VARIETY.**—Single.—1, H. Yardley. 2, T. Fenn. **SELLING CLASSES.**—Price not to exceed 4s.—Pair.—1, J. R. Bailey. 2, A. P. Byford. *vhc*, F. Green. Price not to exceed 3s.—Single.—1, T. Roper. 2, A. P. Byford.

### CHIPPENHAM POULTRY SHOW.

THIS annual Wiltshire gathering was held on the 24th inst., and was a success as far as regards visitors, though the entries were small. This, probably, is to be accounted for by the fact that Swindon, only a little way off, also had its poultry show on the same day, where the classification was better and the prizes more liberal. We were sorry to find only three pens of *Dorkings* at Chippenham, but the first-prize pen contained a pair of good-coloured birds, and which would not have disgraced any show. *Cochins* were better represented, a good pen of Partridge chickens coming in for premier honours, and almost equally good adult Whites second. In *Brahmas* a fair pen of Darks were first and Lights second, the latter in good condition and large. *Polands* again made a small class, but the first and second Silvers were very good and well crested. They were entered at very low prices, and afforded a good bargain to any of the many yeomen's wives who were there, and who might be taken with the "fever." *Game* were excellent—far above the average of local shows, the winning birds being well shown and of much merit. *Game Bantams*, too, were good, and the winning cockerel was very smart in head and carriage. There were only two pens of *Spanish*; the Bristol pair were an even pair of birds all round. The Variety Bantam class was interesting, and the Blacks were very good indeed. The Variety class was a large one and the quality excellent. A very good pen of Malays came in first. They were in hard feather and well standing in their pens. We noticed, too, a good pen of *Silbies*. Cross-breeds had a class, but it was not well responded to, and only five pens appeared. The *Geese* and *Turkeys* were very good, the first-prize pen of the former being as good as we have seen for a long time. *Rouen Ducks* were capital, and so were *Aylesburys*. The latter first-prize pen were good in bills, but not very large. In the Variety Duck class a lustrous pen of East Indians

took first, and a pair nearly as good belonging to the same owner second. A sweepstake for the best *Game* cock finished the catalogue, where the Society added 20s. to the entrance fees, and the whole was to be divided into three prizes. Only three pens were entered, but the winner was a good Red, stylish in shape with fine carriage. We give the awards below. Mr. Hewitt judged, and we believe all approved of his awards.

**POULTRY.—DORKINGS.**—1, Miss J. Milward. 2, G. Hanks. **SPANISH.**—1, Mrs. Tonkin. 2, E. Winwood. **GAME.**—Black-breasted and other Reds.—1, F. Warde. 2, W. H. Stagg. Any other variety.—1 and 2, F. Baily. **COCHINS.**—1, H. Haddrell. 2, Mrs. J. T. Holmes. **BRAHMAS.**—1, Morris & Cameron. 2, Mrs. J. T. Holmes. **HAMBURGHS.**—Gold or Silver-pencilled.—1, H. H. Thompson. 2, J. Orlema. Gold or Silver-spangled.—1, T. Reeves. 2, Rev. R. M. Ahe. **POLANDS.**—1 and 2, J. Hinton. **BANTAMS.**—Game.—1, E. C. Phillips. 2, J. Andrews. Any other variety.—1, Morris & Cameron. 2, Mrs. J. T. Holmes. *vhc*, R. Wignfield. **ANY OTHER DISTINCT BREED.**—1, J. Hinton. 2, S. Spinke. **CROSS BREEDS.**—1, Rev. N. Ridley. 2, J. S. Maggs. **TURKEYS.**—1, F. Warde. 2 and *vhc*, Mrs. G. B. Elliott. **GEES.**—1, G. Hanks. 2, A. M. Murphy. **DUCKS.**—*Bouen*.—1, F. Warde. 2, Miss L. Fennell. *Aylesbury*.—1, J. Lewis. 2, W. Kent. Any other variety.—1 and 2, G. S. Salisbury. *vhc*, W. R. Rootes. **SWEEPSTAKES FOR THE BEST GAME COCK.**—1 and 3, W. H. Stagg. 2, J. T. BROWNE.

### PIGEON COTE.

THE front of the Pigeon room, or cote, should have a south-west aspect; and if a room be selected for the purpose, it is usual to break a hole in the roof of the building for the passage of the Pigeons, which can be closed at convenience. A platform is laid by a carpenter at the entrance for the Pigeons to alight and perch upon, with some kind of defence against strange cats, which will so often depopulate a whole dovecote.

The platform should be painted white, and renewed as the paint wears off, white being a favourite colour with Pigeons, and also most conspicuous as a mark to enable them to find their home. The boxes also should be so coloured and renewed as necessary, for which purpose lime and water will be sufficient. Cleanliness is one of the first and most important considerations; the want of it in a dovecote will soon render the place a nuisance not to be approached, and the birds both old and young will be so covered with vermin, and besmeared with their own excrement, that they can enjoy no health or comfort, and mortality is often so induced. Ours were cleaned daily, thoroughly once a week; a tub standing at hand for the reception of the dung, the floor covered with sifted gravel, often renewed.

Pigeons are exceedingly fond of water, and, having a prescience of rain, will wait its coming until late in the evening, upon the house-top, spreading their wings to receive the refreshing shower. When they are confined in a room they should be allowed a wide pan of water, to be often renewed as a bath, which cools, refreshes, and assists them to keep their bodies clear of vermin. In the attendance upon Pigeons caution is necessary with respect to their fighting, to which they are more prone than might be expected, often to the destruction of eggs or young, or driving the weakest away.

The common barrel dovecote needs no description, at the same time is adapted to every situation in which it is desirable to keep Pigeons for ordinary use. To return to the room or loft; the shelves should be placed sufficiently high for security against vermin, a small ladder being a necessary appendage.

The usual breadth of the shelves is about 20 inches, with the allowance of 18 between shelf and shelf, which will be sufficient not to incommode the tallest Pigeons.

Partitions between the shelves may be fixed at the distance of about 3 feet, making a blind by a board nailed against the front of each partition, whence there will be two nests in the compass of every 3 feet, so that the Pigeons will sit in privacy, and not liable to be disturbed. Or a partition may be fixed between each nest—a good plan, which prevents the young from running to the hen sitting over fresh eggs, and perhaps occasionally to addle them; for when the young are about a fortnight or three weeks old, a good hen will leave them to the care of the cock and lay again.

Some prefer breeding holes entirely open in front, for the greater convenience in cleaning the nests; but it is from those that the squabs are likely to fall, hence a step of sufficient height is preferable. The tame Pigeon seldom taking the trouble to make a nest, it is better to give her one of hay, which prevents the eggs from rolling; or a straw basket, or unglazed earthen pan, may be placed in every nest, apportioned to the size of the Pigeons you breed.

A pan of 3 inches high, 8 inches over the top, and sloping to the bottom like a basin, will be of sufficient size for a Tumbler or a small Pigeon, whilst one of double those dimensions will be required for a large Runt. A brick should always be placed in contiguity to the pan, to enable the cock and hen to alight with greater safety upon the eggs. The Pigeon trap on the house-top is the well-known contrivance of those London rascals, who lie in wait, as has been said, to entrap the property of others. A trap of another description, and for a very different purpose, is sometimes used; it is an area, on the outside of a building, for the purpose of confining in the air valuable breeds of Pigeons which cannot be trusted to flight. Some are erected to the extent of 20 yards long and 10 yards wide, with shelves on every

side for the perching of the Pigeons; thus they are constantly exercised in the air, retiring at their pleasure to the room or loft within.—(*American Fanciers' Journal*.)

### MOVEABLE VERSUS FIXED COMBS.

YOUR esteemed correspondent Mr. J. E. Briscoe recently gave an interesting account of how he had reaped the large harvest of 144 lbs. finest super honey from one Stewarton colony this last season, and drew a comparison of the yield from such frame hive with moveable combs, to the fixity and heterogeneous contents of large straw skeps advocated by Mr. Pettigrew as the *ne plus ultra* for successful bee-keeping. The soundness of Mr. Briscoe's hypothesis has been called in question by Mr. Pettigrew, who has repeatedly referred to me, and I desire to reply.

I would premise at the outset that Mr. Pettigrew's persistent efforts to discover the usual sulphur-pit termination of the common skep system is worthy of all praise. That gentleman says he has never condemned the Stewarton hive; possibly not, but what detracts much from the charm of his interesting communications is a tendency, if I may use the expression, of inferentially disparaging what he has had little or no experience of. The frame-hive question being a case in point. The large harvest of 1868 is probably what Mr. Pettigrew refers to as that of 1864, when in the former capital season I reaped, as detailed in this Journal at the time, from one Stewarton colony ten octagon supers weighing net somewhere close on 200 lbs. This season from two such old colonies and two prime swarms hived singly, and thanks to "mobilmism," into empty-combed frames, I harvested first four, then nine, last eight, in all twenty-one octagon supers free from one cell of pollen or yet brood. The old colonies were quite independent of all that early summer feeding of which Mr. Pettigrew tried with his straw hives, and neither they nor yet the swarms had the slightest extraneous aid whatever in accomplishing their task, saving narrow strips of embossed wax sheets to ensure straight work and plenty of warmth. The last four supers I may add were not sealed-out; and I subsequently regretted that, owing to the season coming on us all so much of a surprise, and much of the honey having been given away in presents, I cannot give the weights with so much exactness as did Mr. Briscoe, saving of what went to market, over 2 cwt. finest super honey. The best colony of 1876 gave nine supers against the ten of 1868.

It is manifestly even more unfair to draw a comparison of the capital harvest of 86 lbs. obtained by Mr. Fox from a straw hive in Devonshire, and the 30 lbs. obtained by Mr. Briscoe with his Stewarton in Staffordshire in the poor season of 1875, as it is to contrast my harvest with that of the Carlisle people. These figures speak as to district, not hives. Let the bee-masters with their hives change places, and see the different results. Rather put it as a rule-of-three question. If a straw skep yields 86 lbs. in south Devon, what would a Stewarton colony there give? To fairly compare results, one hive with another, it is obvious they must occupy a common field. Mr. Pettigrew will say this is mere advocacy, he wants "facts;" I have pleasure in adducing them.

In the same poor season of 1875 there stood in my apiary on stand No. 10, a swarm of the preceding year, hived in two 7-inch Stewarton boxes, and side by side on No. 11 a swarm of the same year, located in a roomy straw skep, both possessing queens of 1874, each having an overflowing population, and being so well matched induced me to prevent No. 11 from swarming and test the two together as depriving hives. Both got full and began to build-out at the same time. The Stewarton was naded with a 4-inch octagon eke, and supered as required; the straw hive was heightened also with first, a 4-inch circular eke, and then another same depth. About the same time No. 10 took to the supers. The only top I could get to sit conveniently on straw was a large Abingdon glass, and with a little frame guide comb induced the bees to take possession at once, and keeping it well covered-up with woollen, comb-building made rapid progress, and at the close of the season the harvest gleaned by the two was as follows:—

No. 10. Stewarton ....	1 octagon super, gross	23½ lbs.
" " ....	1 " " "	17½ "
" " ....	1 " " "	14½ "
" " ....	1 " " "	12½ "
	4 " "	68

No. 11. Straw skep .... 1 Abingdon glass comb  
without stalk and not sealed-out.... 21½ lbs. gross.

I expected the shortcoming of super honey from straw would be greatly made up by supposed greater weight in the skep, but just after removal of supers I chanced to receive a visit from the Vice-President and then Secretary of the Caledonian Apian Society, and on showing them round my apiary pointed out the test hives, reporting the harvest as above, when it was proposed to estimate their then respective weights, and the former gentleman kindly undertook the duty, and to my surprise

pronounced the straw hive light and in want of immediate feeding. He then turned his attention to the Stewarton colony, and drawing it along the board, in his endeavour to raise the heavy weight induced such a sortie from the triple entrance, the Italians using their stiletto with sufficient vigour to put us all to the right-about, and my good friend the President coming in for so terrible a share of the punishment, that should these lines catch his eye, I have no doubt he still preserves a lively recollection of my competitive hives. Mr. Pettigrew may say he advocates the swarming, not the depriving, system. Would that have bettered the matter? Suppose No. 11 had thrown a couple of swarms there would have been no honey at all harvested before even the accustomed autumnal feeding time came round. Such would have shared the fate of all swarms in our neighbourhood, uncared for and been dead, so exceedingly bad was the season of 1875.

When I perused Mr. Pettigrew's statement to the following effect, "In Glasgow, where most of the octagon boxes of comb from the Stewarton hives are sold, there is a demand for twenty times more run honey than there is for comb. If Mr. Briscoe lived in the neighbourhood of Glasgow, the best market in the world for run honey, would he condemn the hives and system that helps greatly to meet the demand?" From passing familiarity with the appearance of the Glasgow honey warehouses, I felt that that gentleman had been most egregiously misinformed; and as Mr. Briscoe had not the same opportunity, from nearness of residence felt it incumbent on me to collect a few "facts."

My first visit was to one of the oldest honey warehouses. I found from the manager that when they had more of a monopoly there, turnover would be about three hundred boxes of comb, against twenty to thirty pints of run honey. Still they did a large trade in comb, a little in French run honey, Scotch run honey being little asked for. The next party called upon does a considerable wholesale as well as retail business. Estimated his sales would be about two supers (38 lbs.) comb against one pint (5 lbs.) of run honey. He had paid the grower on an average for the last five years 1s. 6d. per lb. for comb and 10d. for run honey. He did nothing in foreign. My third call elicited a capital sale for honeycomb; run honey they did little in, saving a few glass bottles finest comb run honey by themselves, west-end ladies being very fastidious about the cleanliness of run honey, preferring seeing it clear through glass. The fourth merchant told me the figures in the Journal should have been reversed. He sold a little run honey in families for colds, but for table use in Glasgow honeycomb was the correct thing. So much for statistics, which require no comment. No doubt "in the second city of the empire" a large quantity of run honey must of necessity find its way into other channels, such as the confectioners and drug stores; but I am informed the cheap foreign honey cask meets that demand.

As Mr. Pettigrew very justly remarks, "It is an important question, and cannot be too fully discussed." But as I have already encroached too much on valuable space with details, must defer till next week a more general view of the question at issue.—A RENFREWSHIRE BEE-KEEPER.

### QUEEN BEES.

THE concluding paragraph in "B. & W.'s" article of November 16th, on the exchange of queens, where he says, "The two queens may have met, and the Italian proved herself the stronger," leads me to pen these few lines to express a doubt whether such an occurrence is at all necessary, or even likely to occur, in order that the intruding queen should suffer the penalty of death. The more I learn about bees the more conviction forces itself on me, that many statements recorded and repeated again and again about them are fallacious. I do not accuse observers of wilfully deceiving, but some new or wonderful occurrence is seen, or believed to be seen, when it is at once recorded as a habit of the bee. Mrs. Tupper has said "bees do nothing invariably;" nothing could be more true, and sometimes they do things which at the time are to us wholly unaccountable. To exchange a queen is a common operation with me, and my experience is that, as a rule, to release one six or seven hours after caging would be found a most dangerous proceeding. Last month, when the weather was very cold and likely to continue so, I risked the introduction of two queens without any caging simply because I did not want the stocks chilled. The first stock, which had been queenless some time, killed their new sovereign; the second, where I merely took out their own queen and dropped the other in her place, accepted her all right, and she lives still. Now, had my opinion been asked as to what would occur I should just have reversed the events.

The introduction of a strange queen into a hive where one already reigns, I do not believe troubles the latter whatever. I have put in scores and find the result as follows:—The first bee which discovers the intruder seizes her by the leg or wing and holds on, and then comes another and another until she is covered; still the bees crowd on, holding to one another until a

solid ball as big as a bantam's egg is formed, with the queen in the midst. A vigorous hissing is kept up, and so intent are the bees on their attack that the ball of bees may be taken up into the hand without any fear of stinging. At the Alexandra Palace Bee Show I several times caused the formation of such a bee ball, which was handed round among the spectators from hand to hand. I find the workers rarely sting a strange queen: they will keep her encased until she dies or their fury abates, and then release her. I have known one confined in this manner for a fortnight, when she died; it is certain they must at least sometimes feed the prisoner, for a queen will die of starvation in twelve hours. So eager are the bees to encase a new queen, that if the latter be held by the wings with the thumb and finger, the bees will gather there into a ball. I have said workers rarely sting a queen, but they do sometimes. I have seen almost the first bee that perceived her jump on her back and sting her in an instant, when she would quickly die—not always, however, for twice have I seen a queen stung and the sting left in her, and yet no fatal result occurred.

Remembering the old tale of how the reigning queen would seek out an intruder, some two or three years ago it occurred to me what an easy way it would be to extract the old queen from a skep to substitute a new one if I first caged the latter in the hive. I tried it several times, but in no instance did ever I find the old queen come to my bait. Several times when wishing to preserve a queen for a few days I have caged her in the midst of a populous hive, where she obtained food and warmth. I never found the reigning queen trouble herself, although the cage would be sure to be thickly covered with the excited workers. I am also sceptical as to the invariableness of fighting to the death between queens which meet. If we put two queens under a wingglass, and watch the result, we see them seize each other, wrestle and fight like two gladiators, and sometimes one receives a sting and dies, but more often they separate, again come together for another battle with still a negative result. This is repeated until they get tired of fighting and let each other alone.

Twice this year I came across instances of two queens in a hive, but I do not think in either case they were both fertile. In the first instance, the old queen was evidently worn out. She had bred an inordinate number of drones—no hope of a swarm; yet instinct guided the bees to raise a young queen, which soon took the place of the old one, which I found thrown out of the hive. I once divided a hive by a diaphragm of perforated zinc, filled each half with combs and a swarm, gave entrance to one colony in front, and to the other at the back of the hive. It was no use. One queen went on with her maternal duties, the other was encased by her own bees. I caged and released her several times but in vain, the bees had evidently made up their minds it was *one* hive, and therefore they would not have *two* queens.—JOHN HUNTER, *Eaton Rise, Ealing.*

### ITALIAN VERSUS BLACK BEES.

This is my third year's experience in bee-keeping at this place. I commenced with eight stocks of Italians. I bought fifty stocks of black bees from different parties and italianised about one-half of them the first season. I put boxes on the hives during buckwheat, and to my surprise the black bees were the first to commence in them, and gave me by far the best yield, though the Italians were the strongest. The next season I put on the boxes early and gave the Italians every advantage, but the blacks were the first to commence, and kept a-head all the season.

This season I commenced with sixty-five stocks, about one-half of them were Italians and hybrids. Commenced boxing during fruit bloom, but the weather was cold and windy. None commenced in boxes till white clover, June 5th. The clover season ended July 5th, and was the best I ever knew while it lasted. My best stock of black bees put up 150 lbs. of white honey in 4-lb. boxes, while the best Italians put up 120 lbs. Several stocks of blacks went from 100 lbs. to 150 lbs. Only one Italian reached 100 lbs., yet the stocks were all strong and in good condition in the spring. After this experience I am forced to the conclusion that as box workers the black bees are the best. Where the extractor is used the Italians are all that is claimed for them. I use the extractor only as a necessity. Box honey is my hobby. Bees have just commenced on buckwheat; the prospect is good for a fine crop.—JOHN VANDERVOEST.—*American Bee Journal.*

### FRAME HIVES VERSUS SKEPS.

Let me assure Mr. Pettigrew that the statement of the Swiss gentleman he quotes, that frame hives are on their trial in Germany or America, is incorrect. It is true as to France, and of Switzerland I know nothing; but in America skeps are now unknown. Some few use boxes, others hollow logs of wood, but I think I may venture to say that all who pursue bee-keeping

there as a trade, and there are many hundreds who do so, use frame hives. One of the leading bee journals lately remarked with surprise that a well-known English firm still exhibited straw hives! In Germany, wherever bee-keeping is pursued largely frame hives are used. My correspondent, Baron Ambrosy of Hungary, sent me a photograph of his apiary, which contained 1290 hives all with frames. I think Mr. Briscoe is quite correct in saying that "all scientific apiarists of Europe and America have adopted some modification of the bar or bar-and-frame hive."—JOHN HUNTER, *Eaton Rise, Ealing.*

### OUR LETTER BOX.

LEGHORNS (*H. J. B.*).—We presume that you mean these varieties of poultry. We never heard of fowls of the name you have written. Leghorns may be managed the same as Silver Hamburgs.

AMATEUR PIGEON CLUB.—"W. S." wishes to know if there is one in the neighbourhood of London formed for the purpose of training and flying Pigeons as the sport is carried on in Belgium.

DRIVING BEES (*T. Jones*).—You will find full directions in our "Bee-keeping for the Many." You can have it free by post if you enclose five postage stamps with your full direction.

GALLON (*W. H. Attwood*).—There are 282 cubic inches in a gallon.

### REMARKS.

22nd.—Fair, but rather hazy morning; very dull all day, but without rain.  
23rd.—Dull and dark (though without rain) all day; rather cold at night.  
24th.—Dull and dark at 9 A.M., but fine and bright by 10 A.M.; rain at 1 P.M., and showerly after.  
25th.—Rainy forenoon, dry afternoon; fine at night, wind very high for a short time about noon.  
26th.—Fine morning, but heavy shower about noon; damp, though not raining all the rest of the day.  
27th.—Rain in the night; damp, dull, and dark at 7 A.M., and so continued all day.  
28th.—A remarkably fine, bright, pleasant day throughout; lunar halo in evening; rain at night.  
A colder week than the previous one, and very damp.—G. J. SIMONS.

### COVENT GARDEN MARKET.—NOVEMBER 29.

THERE is no improvement in our market this week, all classes of goods having a very slow sale. The supply of Grapes has fallen off, and good samples of late sorts will now fetch better prices. Pines are dull. A fair business in Kent Cobs doing at last week's rates.

From observations taken near London during forty-three years, the average day temperature of the week is 46.0°; and its night temperature 35.1°.

## INDOOR EARLY WINTER FLOWERS.

OUTDOOR supplies of flowers for filling vases are cut off by frost and snow, plants now flowering naturally are not numerous, and forced plants are not yet in beauty. The demand for flowers, instead of decreasing as the days become shorter and duller, increases. Flowers never make their presence felt more than in the dull autumn and early winter months, and at no time in country establishments are they more in request. The shooting and hunting season generally strains the resources of the garden. No wonder that the cultivation of plants with handsome foliage of bright glowing colours should have received an impetus. Ever flower-like in colour, ever beautiful, they are always available for decorative purposes. Yet useful as are their sprays for cutting we must still have flowers. Take a friend's opinion. "All the colours sought for formerly in the flowers of plants must now be looked for in their foliage; and if the present rage for coloured-leaved plants continue it will soon be difficult to find a plant with plain green leaves and showy flowers. Variegated plants have frequently a diseased look—anything but the freshness of Nature's green heightened in effect by her bright glowing flowers." That observation struck me as conveying a hint that leaf-colouring may be overdone; that we might have too much coloured foliage, and too little green leafage contrasted with bright flowers.

It is a fact that few plants which are noticeable for beauty of foliage are remarkable also for handsome flowers, and when flowers are produced in anything like profusion on variegated plants they do not appear to advantage with the beauty of the leafage. The effect of mixing variegated leaves, or sprays of variegated plants, with flowers is very similar to that of flowers upon a variegated plant. They do not accord well together, though the white inflorescence of *Iresine Herbstii* is effective in contrast with the red foliage; the plume-like *Celosia* flowers intermingled with bold variegated foliage have a particularly fine effect; and the sprays of *Panicum variegatum* will almost associate well with anything, and at this its flowering season its crimson inflorescence is quite charming. It shall therefore have the first place upon the list for its general usefulness and adaptation; and as I do not intend to dwell particularly on variegated-foliaged plants, I should like to make but one suggestion—namely, if flowers are at any time scarce never let the scarceness be felt, but seek to meet a lack of flowers by bright glowing leaf-colouring. Many overgrown or ill-shaped plants may often be laid under contribution with advantage even to the plants, and certainly to the credit of the gardener.

I will now note what I find to be useful as early winter-flowering stove plants. *Hippeastrum pardinum* is now (November 21st) in full glory, its crimson-red spots on the cream ground being very beautiful. Just going off are *Hippeastrum robustum* and *Amaryllis aulica platypetala*, red, tipped green, yellow-striped. What

others of this family will flower without any special treatment in a stove? The beauty and distinctness of *Amaryllis* cause them to be always acceptable. *Urceolina aurea*, with its bright yellow and green-tipped drooping bells, is a very desirable early autumn-flowering bulbous plant of the easiest culture, and continues flowering throughout November. It is seldom that the *Griffinia Blumenavia* or *G. hyacinthina* are seen, but finer winter-flowering bulbous plants are not grown. Their flowers are Lily-like, produced in elegant heads, the former having white pink-striped flowers, and the latter blue flowers, and the plants are evergreen—at least as much so as are *Eucharises*.

*Geniera macrantha* is another valuable early winter-flowering plant; it has a root like a *Gloxinia*, very clear-green leaves, and a fine head of bright scarlet flowers. It requires to be started in June. The long panicked racemes of orange-scarlet flowers of *G. zebrina splendens* are fine, and as they come from the axils of the leaves after the principal flowers are past the plants continue a long time attractive. *G. cinnabarina* has very beautiful leaves and fine red and orange flowers; but *G. exoniensis* from its dense growth, high-coloured leaves, and profuse blooming properties is the most desirable. Its flowers are orange-scarlet, with a yellow throat. *Achimenes*, and especially *Tydeas*, not started until June, will flower finely in early winter. I find the small but numerous bright scarlet flowers of *A. ignea* very useful for cutting. The flowering sprays have a light appearance. Amongst *Tydeas* I find *Display* a splendid variety.

Few plants are more free in flowering in winter than *Begonia nitida odorata*, white tinged flesh, which does best upon a trellis against a wall; *B. insignis*, pink; *B. Weltoniensis*, pink; *B. erecta multiflora*, pink; *B. fuchsoides*, scarlet; *B. parviflora*, white; *B. hybrida floribunda*, bright rose; *B. Saundersiana*, flesh; *B. Ingrami*, salmon, all from cuttings struck early in April and grown-on make fine plants by autumn, blooming all the winter in a stove.

*Allamanda neriifolia* flowers more or less continuously; and late-started plants of *A. nobilis* and *A. cathartica* give their gorgeous blooms up to Christmas. *Clerodendron Balfouri*, which was given a rest in August and kept moist after the middle of September, is now showing its cymes of white calyxes with their peeping crimson corollas. *Passiflora princeps* keeps up a continuous supply of its rosy scarlet flowers; and the glowing *P. kermesina* is of the brightest scarlet-crimson suffused with violet. *P. Madonna* also is a fine plant for early winter, producing its flowers freely.

*Centropogon Lucyanus* with red flowers is free and effective; and a pretty bushy graceful plant is the easily-grown *Centradenia rosea*, dotted with its rosy stars. Then we have the rosy-pink bracts of *Dalechampia Roezliana* rosea, and the fiery orange scarlet of *Aphelandra aurantiaca* Roezli, *Jasminum Sambac flore-pleno*, white; *Eranthemum pulchellum*, blue; *Thysacanthus rutilans*, scarlet; *Scutellaria Mocciniana* and *S. pulchella*; the very desirable *Tabernaemontana coronaria flore-pleno*,

white; *Poinsettia* with scarlet and white bracts; also the scarlet *Euphorbia jacquiniæflora*, *Pentas kermesina*, deep rosy pink; with the fiery rose or scarlet of *Plumbago coccinea* *superba*, and the deep violet of *Lasiandra macrantha floribunda*; *Ipomæa Horsfalliæ* with its glossy-lustred rosy crimson flowers, and the orange red and yellow of *Manettia bicolor*.

*Rogiera gratissima*, with its fine white heads of bloom, with *Luculia gratisima*, are perhaps the finest of early winter greenhouse plants for cutting; they are best planted out, and succeed well in an intermediate house, as also do *Epiphyllums*, *Libonia floribunda*, *Monochætum ensiferum*, and the fine evergreen bulbous plant *Imantophyllum miniatum*, which usually flowers at this season.

Cool greenhouses are now gay with *Chrysanthemums*. I hope to refer to them again. Our friend's remarks on coloured foliage certainly do not apply to greenhouse plants. If anything there is a paucity of high-coloured foliage in greenhouse plants, except in the Zonal section of variegated *Pelargoniums*. Zonal *Pelargoniums* cut-back in June and grown specially for early winter decoration are exceedingly valuable. In a temperature of 50° they continue flowering most of the winter. Carnations and *Bouvardias*, if the flowers are meant to be had with certainty, must have an intermediate temperature midway between that of a greenhouse and stove; yet I have Carnations more or less through the winter without extra heat.

*Camellias* commence flowering early in November and continue up to April; they never leave the house. *Lady Hume's Blush* is generally the first to open, and for ladies' hair there is no finer variety excepting buds half expanded of *C. fimbriata*. *Primula sinensis* vars. are never finer than in early winter, flowers of the double kinds being grand for bouquets, and the plants for table and general decorative purposes. *Cyclamens* I find superior when raised from seed and not keeping the plants after the third year. *Cinerarias* sown early now flower well, but are not nearly so good as they will be in March and April. Yellow flowers are given at this season by *Acacia platyptera*, *A. alceifolia elegans*, and *A. armata*. *Abutilon Boule de Neige* has white bells after the style of *A. venosum*. *Polygala oppositifolia* is one of those few plants that keep on growing and flowering from the end of every shoot, and the very pretty *Leschenaultia formosa* must not be omitted. *Statice profusa* is always forthcoming in lavender, and *Schizostilis coccinea* in blood colour; and we have the fiery scarlet of *Tropæolum Triomphe de Gand* and others that bloom the winter through in a greenhouse. The long, white, waxy tubes of *Rhododendron jasminiflorum* attract by their loveliness, and *Correas Brilliant*, *magnifica*, *cardinalis*, and *Harrisii* always flower in November and December. Roman *Hyacinths* as greenhouse plants are very desirable, and the best blue flowers to associate with the white *Hyacinths* are *Myosotis dissitiflora* and *Ageratum Imperial Dwarf* or *Countess of Stair*, the latter being deeply tinged with purple.

Heaths—everybody likes Heaths—are represented by *Ericas Lambertiæ* and *L. rosea*, *hyemalis*, *gracilis autumnalis*, *caffa*, *colorans*, *arbuscula*, *canaliculata*, *pyramidalis*, *melanthera*, *Willmoreana*, and *Willmoreana rosea*; and of *Epacris* we have *ardentissima*, *delicata*, *The Bride*, *Eclipse*, *carminata*, *Devoniensis*, *hyacinthiflora*, *Lady Panmure*, *impressa coccinea*, *Viscountess Hill*, and *hyacinthiflora candidissima*.

There are many plants that I have omitted, especially in Orchids, as *Calanthe vestita* vars., *Odontoglossums*, *Dendrobies*, *Zygopetalum Mackayi* var., and many others, few being easier grown and certain than *Limatodes rosea*.—G. ABBEY.

### WATERING IN WINTER.

I saw the other day an answer to a correspondent stating that "Peach trees do not require as much water in winter as they do in summer." I do not dispute this advice for a moment; but still I maintain that to allow Peaches or any other trees to become dry during winter does them an immense deal of harm. They do not absolutely require as much water because there are no leaves to evaporate it, but they do require the soil to be as moist in winter as at any other time, and I may say that in my own practice the soil is often wettest during winter indoors as well as out, for which I will give my reasons.

My manure-yard, like most others, is not covered, and when heavy rain comes a great deal of the strength of the manure is washed out, and would be lost if I did not take the precaution to catch it in a hole for the purpose. In summer there is not so much as I should like to apply to plants which are

growing vigorously, but in winter there is more than is required. My fruit borders are not rich, as I hold it to be a mistake to make them so for young trees, which generally grow too vigorously anywhere. The borders are well drained, and the soil is of the simplest nature possible, consequently they will last a long time, and when once the trees attain a fruiting state they will bear any amount of feeding. Well, then, as Nature in her wisdom applies as much water in winter as she does in summer, it is plain that, provided the roots are in a suitable medium, it will do no harm to copy her in this respect. And in practice I find it is not essential to have the water perfectly pure. The manure water is not confined to the houses, but is applied to fruit trees of all sorts as soon as they reach the bearing state, and is commenced with as soon as the wood is fairly ripe in autumn. It should not be applied late in summer while the trees are growing, or it will retard their ripening.

What a change has taken place in the horticultural world within a few years as regards border-making, watering, drying-off, ripening, notions about periods of growth, periods of rest, &c.! It is not many years since Dr. Lindley judged of the quality of a fruit border by the looseness of its material, and thought he had found perfection when he thrust his walking-stick up to the handle into the soil of a Vine border; and he no doubt tempted many to imitate such a border. Now-a-days any practical gardener would ridicule such a notion, and work in almost an opposite direction. A little further on, when the great man saw that the Vine roots darted as straight as an arrow through such a border and ramified in all directions in the gravel walk beyond, he came to the conclusion that the gravel walk was the best medium for them. Here was another instance of theory without practice leading astray one of the best men of our day.

The drying-off process received a severe shock a few years ago when *Cyclamens* were first shown so splendidly from Twickenham, Isleworth, &c., and it was proved that instead of growing and starving alternately for four or five years to get them into a presentable condition, that the work could be better done and more satisfactory results obtained by growing them vigorously for twelve or fourteen months. Drying-off is getting more and more into disrepute every year, and we now see it recommended that even Dutch bulbs should not be kept dry a day longer than is necessary for their journey. It is still recommended by some to dry-off *Amaryllis* and other similar plants; but this will be exploded before many years, for in my practice I find that *Amaryllises* grown in a greenhouse temperature and ripened by placing them outdoors in summer, without ever stinting them of water, flower two or three times a-year, and always have foliage when they do flower. I have many bulbs so treated which are from 18 to 20 inches in circumference.

There is no such thing as a total rest for a plant unless it is receiving injury at the same time. Deciduous plants are growing all through the winter, except when they are frozen or their roots are not in a suitable medium. The nearest approach to a state of rest is when the leaves are falling, and even the leaves are often pushed off by the expanding buds. Deciduous plants used to be treated as if they were as dead as deal boards for two or three months; happily they are not treated quite so badly now, but there is still much room for improvement.—WILLIAM TAYLOR.

### ROSES FROM AN AMERICAN POINT OF VIEW.

#### THE LAST ELECTION.

READERS of the Journal, American as well as English, cannot but feel grateful to Mr. Hinton for bringing about the Rose election lately held. The table, into which is condensed the results of the election, is extremely interesting and instructive.

In looking it over I do not find as many of the Teas included as I expected. We are also surprised to note the high position occupied by *Devoniensis* and *Souvenir d'un Ami*, lovely varieties of the class, but not at all exhibition varieties. *Rubens*, a large and very beautiful sort, is not once named; and the charms of *Marie Ducher*, *Madame Trife*, and others are also ignored.

Among the Hybrid Perpetuals *Comtesse Cécile de Chabrilant* occupies a very low position. We cannot understand the reason of this. True, the flowers are not large, but the perfect form, robust habit, and delightful fragrance are a combination of excellencies equalled by few Roses. In selecting a perfect Rose we must have regard to colour, form, fragrance, hardiness, vigour, and free-blooming properties. Excellency in the

first two qualities is essential, and in the others desirable. Judged by this standard Comtesse de Chabrillant is a model variety, and accordingly we enter a respectful protest against the low position assigned her by the electors.

General Washington we would suppose worthy a place among the chosen fifty. The flowers are large, very full, and are produced in great abundance. The idea of attaching raisers' names, and the year when a variety was sent out, is a very useful feature of the table, and greatly to be commended. We append our list of the best fifty varieties:—

Rose.	Age.	Raiser.
1. Alfred Colomb, H.P. ....	1865	Lacharme
2. Catherine Mermet, T. ....	1869	Guillot, fils
3. Charles Lefebvre, H.P. ....	1861	Lacharme
4. Comtesse de Chabrillant, H.P. ....	1859	Marest
5. Countess of Oxford, H.P. ....	1869	Guillot, père
6. Ferdinand de Lesseps, H.P. ....	1869	E. Verdier
7. François Michelin, H.P. ....	1871	Levet
8. Gloire de Dijon, T. ....	1858	Jacotot
9. John Hopper, H.P. ....	1862	Ward
10. La France, H.P. ....	1868	Guillot, fils
11. Louis Van Houtte, H.P. ....	1869	Lacharme
12. Madame Victor Verdier, H.P. ....	1863	E. Verdier
13. Mdlle. Marie Rady, H.P. ....	1865	Fontaine
14. Mdlle. Eugénie Verdier, H.P. ....	1869	Guillot, fils
15. Maréchal Niel, T. ....	1864	Pradel
16. Marie Baumann, H.P. ....	1863	Baumann
17. Marie Ducher, T. ....	1868	Ducher
18. Marie Van Houtte, T. ....	1871	Ducher
19. Marquise de Castellane, H.P. ....	1869	Pernet
20. Rubens, T. ....		
21. Abel Grand, H.P. ....	1865	Damaizin
22. Anna de Diesbach, H.P. ....	1869	Lacharme
23. Baron de Bonstetten, H.P. ....	1871	Liabaud
24. Baronne de Rothschild, H.P. ....	1867	Pernet
25. Belle Lyonnaise, T. ....	1869	Levet
26. Caroline de Sansal, H.P. ....	1849	Hippolyte Jamain?
27. Cloth of Gold, N. ....	1843	
28. Duke of Edinburgh, H.P. ....	1866	Paul & Son
29. Edouard Morren, H.P. ....	1869	Granger
30. Général Jacqueminot, H.P. ....	1858	Rousselet
31. General Washington, H.P. ....	1861	Granger
32. Lamarque, N. ....		
33. Madame Bravy, T. ....		Guillot, père
34. Madame Camille, T. ....	1871	Guillot, fils
35. Madame Levet, T. ....	1869	Levet
36. Madame Lacharme, H.P. ....	1873	Lacharme
37. Madame Marie Finger, H.P. ....	1873	Rainbaud
38. Madame Norman, H.P. ....	1867	Guillot, père
39. Madame Trifle, T. ....	1869	Levet
40. Marguerite de St. Amand, H.P. ....	1864	Sansal
41. Maréchal Vaillant, H.P. ....	1861	Lecomte
42. Maurice Bernardin, H.P. ....	1861	Granger
43. Paul Neron, H.P. ....	1849	Levet
44. President Thiers, H.P. ....	1871	Lacharme
45. Prince Camille de Rohan, H.P. ....	1861	E. Verdier
46. S. Reynolds Hole, H.P. ....	1873	Paul & Son
47. Sénateur Vaisse, H.P. ....	1859	Guillot, fils
48. Sombreuil, T. ....		Robert & Moreau
49. Souvenir de la Malmaison, B. ....	1843	Beluge
50. Victor Verdier, H.P. ....	1859	Lacharme

—H. B. ELLWANGER, Mount Hope Nurseries, Rochester, N.Y.

### AN ELECTION OF APPLES.

As the election of Roses has been concluded in the same manner as other elections—that is, satisfactorily to the winning side and with the usual amount of grumbling on the other, but on the whole more satisfactory than any similar elections on account of the fairness by which it was conducted, cannot we engage in other elections equally important to the horticultural world? For instance, great diversity of opinion exists on the merits of Apples for the various purposes this fruit is used for. Can it not, therefore, be divided into sections, and the respective merits of each variety be fairly pointed out? I may be told that every nurseryman's catalogue does this, but the same is also done with Roses. The question, therefore, arises—Cannot the outside world be also invited to give an opinion? And numerous as may be the growers of Roses, I feel sure the growers of the Apple equal if not exceed them in number, and the claim of utility lies vastly in favour of the Apple cultivators. Would it not, therefore, be well if someone would divide Apples into classes in some intelligible form, and invite the opinions of growers on the merits of the respective kinds adapted for each section? Perhaps some classification like the following might be adopted:—

Class 1.—Dessert Apples from the earliest possible period to the end of August.

Class 2.—Kitchen Apples for the same period.

Class 3.—Table Apples for September and October.

Class 4.—Kitchen Apples for the same period.

Class 5.—Table Apples for November, December, and January.

Class 6.—Kitchen Apples for the same period.

Class 7.—Table Apples for February, March, and April.

Class 8.—Kitchen Apples for the same period.

Class 9.—Apples that are fit for table after April.

Class 10.—Apples fit for kitchen use after April.

Perhaps someone may suggest a better classification than the above, and may possibly advise an exhibition class. My object has been simply a utilitarian one, but I do not object to the introduction of a class for exhibition purposes. Those wishing for such a class would probably prefer the autumn months when the greatest display can be secured, but many modifications may be made in the schedule above given, and it is only sketched as a rough idea on the score of utility. A table might perhaps be drawn up giving the respective position of each variety in respect of its free-bearing character. The Apple is unquestionably the most important fruit we grow, and is well worthy of being studied and its merits being fully made known. I hope to hear as lively a discussion on the merits of the respective varieties as has taken place on that of the Rose. In this early stage it would not be advisable my giving an opinion except in the most general sense, and which may be expressed in the words of an eminent grower near here, who "prefers bushels to dozens." The meaning of this will be understood by most people. In conclusion I strongly advise a competitive election of the best varieties of this most useful of all fruits, and hope it will be the means of pointing out the best we have in cultivation adapted for the various purposes set forth.—J. ROBSON.

### ROYAL HORTICULTURAL SOCIETY.

As you have been good enough to issue a supplement slip on the subject of the Royal Horticultural Society, allow me to say a few words upon it.

We have now a long and influential list of names of the best horticulturists throughout the country of all ranks, from peers to professional gardeners, who are willing to join our committee, or to be guinea Fellows or patron four-guinea Fellows of the Society when reconstituted, and they cordially support the movement. Had we time enough before us the influence of their names would be powerful enough to bring in the number of guinea Fellows we require. The end of the present state of things cannot now be far off. May I, therefore, urge upon all who have almost made up their minds to join us to do so at once, and to use their influence over friends to make them do likewise?

It may be said that the appeal should have been made by the Council as the governing body, and not by either a self-constituted committee or by individuals. But the Council is in a not very easy position. Some of its body approve of the guinea fellowships, others do not; others doubt if sufficient numbers will be forthcoming. They may think that out of the number of two and four-guinea Fellows now in the Society a considerable number may, from old association, or from good will, or from force of habit, continue their subscriptions after the gardens, for the benefit of which they at first subscribed, have been given up; that guinea fellowships might disturb these subscribers, and that thus one probability might be sacrificed for another.

It is different with an outside committee and with individuals. I am convinced that guinea fellowships and patron four-guinea fellowships will give the strongest form of Society and will enlist the good feeling of the whole country, and that the necessary numbers can be shown to be forthcoming. I believe the most practical course now to take is to concentrate our efforts to bring in enough would-be Fellows from all parts of the country to make a Society representing those who love gardening, and those who have most studied or take the greatest interest in gardens and in horticultural science.

The experiment in this district has proved that there are abundance of owners of gardens in the country ready and willing, if asked, to form a Society with a sufficient revenue for all our wants. Letters in answer to the circular, which has now been widely distributed, show that in England, Scotland, Ireland, Wales, and Jersey horticulturists adopt the guinea fellowship, believe that it will produce a strong lasting Society, and are willing to take trouble in canvassing their neighbours.

I for one would advise little change in the present executive. It is both experienced and able. Why, the many good Councils, who have devoted great labour and much more valuable time to the affairs of the Society, with the result only of successive

failures, is not owing to their fault, but to the composition of the Society and to the incumbrances due to this composition.

Of course the Council's object is to make the Society strong and stable, and without the constant changes and dissensions which have been alike the evidence and the cause of its unhealthy condition; and if we can show a sufficiently strong body of the right sort of Fellows who have agreed to join on the new bases, the Council will be only too glad to see a difficult question solved. Therefore let me say again to all good horticulturists, Come in, come quickly, and make others come. If anyone is willing to circulate slips like those which have been distributed, and will ask for them, I shall be most glad (having contracted for 100,000) to forward any quantity. While this was being written the post which came in brought six letters with names of would-be guinea Fellows; two of the number, one from Yorkshire, the other from Leicestershire, asked for circulars to distribute; and two of the names were those of ladies.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath, Surrey.*

### GARIBALDI STRAWBERRY.

In reply to Mr. Bennett of the Rabley Nurseries I can state that the man who claims the credit of raising Garibaldi is Mr. Thomas Armstrong, Belah Gardens, near Carlisle. He sent a few plants of it for trial to Mr. Joseph Hamilton of Botcherby, Carlisle, an extensive fruit grower and market gardener, also a man of much experience, and well known as the founder of the Hamiltonian system of Pine-growing. I believe he considered Garibaldi quite distinct and well worthy of cultivation. At that time, as now, some regarded it as identical with Vicomtesse Héricart de Thury, and no doubt assertions to that effect have prevented its wider cultivation, more especially in the southern and eastern counties, where it seems to be almost unknown; but in the northern counties, around the "merry city" where it originated, and in the south of Scotland, it is extensively grown and, I believe, very much esteemed, being a certain and abundant cropper out of doors, and for forcing one that can always be relied on for a crop.

I have grown and forced it regularly for several years along with other varieties, such as President, Keen's Seedling, Sir Joseph Paxton, Sir Charles Napier, and others, but latterly have given Garibaldi preference for my first; and with me it has been very rare indeed that any of the plants have turned out non-fruiters, and therefore I regard it as a Strawberry of great excellence. I have this autumn young plants of Vicomtesse Héricart de Thury, and next season I shall decide the identity or otherwise of the two varieties. I may say, however, that anyone adding the true Garibaldi to their collection will not be disappointed. If it turn out a distinct variety, to Mr. Armstrong is due the thanks of the horticultural community for raising it; but I fear with that he must be satisfied, as I do not believe he has hitherto reaped much benefit from it, and as it is in the hands of so many dealers and private individuals he cannot hope to do so now.—J. B. S.

### HOW TO GROW THE ROSE.

I CAN best show my gratitude to "R. S." for affording me another opportunity of drawing attention to the subject of the usual ill-treatment of the Rose, by giving him a few hints as to how he may best improve the condition of the Roses in his own small garden.

There are three courses open to him. I will mention each in its order of merit. (1), I would recommend him to devote one small bed, or a portion of a larger one, entirely to the Roses. A space 6 feet by 4 feet will be of sufficient size to give the requisite amount of room. Let the ground in the first instance be trenched to the depth of 2 feet and well manured. Should the subsoil not be sufficiently good the addition of a little turfy loam will be desirable. This addition need not, however, be regarded as altogether indispensable, for I know that rich loam of this character is in some localities difficult to procure. Previous to replanting the Roses their roots will be all the better for a slight trimming, and any suckers that may have formed amongst them will have to be carefully removed. If the Roses are on the Manetti they should be planted 6 inches, and if on the Briar 3 inches deep. Care should be taken that the soil be well trodden down round the stems after planting. Secure the stocks, if standards, to firmly planted stakes, and attach permanent labels to those varieties the names of which are known. These per-

manent labels may be quickly made out of thin strips of deal smeared over with white paint, and written on afterwards with an ordinary lead pencil. (2), Should "R. S." prefer to retain his Roses in the same places they now occupy, he has only to dig them up and replant them in accordance with the foregoing directions. (3), Or he may transfer some of them to a small grass plot, should he possess one, in a similar manner. In the two latter cases it is all-important that no plant or grass should at any time be allowed to grow within 18 inches of the stems of these Rose trees, and that the roots of the removed Roses should not be exposed to the influence of the sun and air longer than is absolutely necessary. Now is the time of year to carry out these simple operations.

I would willingly add some instructions as to pruning when the long-looked-for spring arrives; but as I do not know the names of the varieties in question can only advise a clean cutting-out of all decayed, weak, and superfluous wood, and that the shortening of the remainder be left to the knife of some kind and experienced Rose-loving neighbour.

I infer from "R. S.'s" remarks that his own Roses are situated in the midst of a crowd of other flowers, and that his garden is very limited in size. But even should these inferences prove altogether wide of the mark I do not think the suggestions I have given will be thrown away; for only a few months since might be seen, in every other garden throughout the length and breadth of Rose-growing England, half-famished Roses casting hungry and envious glances across the intervening fences at those more fortunate members of their race who, to all appearances, were in the enjoyment of the most ruddy and blooming health, and living literally upon the very fat of the land.

It is for hundreds of thousands of "miserable starvelings," as Mr. Luckhurst would call them, like these that I again venture to plead; and all I ask for them is a little more room and a rather more generous dietary.—E. M., *Croydon.*

### FLOWER SHOWS AND THE PUBLIC.

It will be very cheering for those of your readers who are earnest supporters of horticultural exhibitions to see that it is not impossible to revive the apparent declining taste for flower shows. The Newcastle-on-Tyne Botanical and Horticultural Society has been in a very low state for the last few years, and had it been in some localities it would have expired before now. It has apparently taken a fresh "lease," and much credit is certainly due to Mr. Taylor and his colleagues for their energy and the success which has crowned their efforts.

It is a pity that Mr. Taylor did not give your readers the secret of success, as it might have proved of much value to men who may unfortunately be similarly situated with other societies. A few weeks ago I saw a circular issued by this Society, but which I unfortunately have not by me, but from what I can remember their new scheme (if it is new) is a similar one to that now being energetically advocated by Mr. G. F. Wilson for the reorganisation of the Royal Horticultural Society, only differing in the amount of subscription. This Newcastle Society gives to every member who subscribes 5s. a pass which will admit him to all shows held by the Society, and a ticket to admit a friend to one of these. The Society purposes holding three shows during 1877, of two days each, so that each subscriber gets for his 5s. tickets to the value of 12s.—that is, supposing his pass to be used for both days of each show, the other ticket being worth 2s. on the first day of either show. As I write from memory I hope I may be excused if I make any mistake. And this is just what Mr. G. F. Wilson wishes to do for the Royal Horticultural Society by introducing guinea Fellows, and I think the surprising success that has been achieved at Newcastle augurs well for the success of the same scheme with the Royal Horticultural Society. I hope it may be equally satisfactory.

There is one matter wherein I think the Newcastle Society makes a mistake—viz., allowing an exhibitor to set up as many stands as he chooses for one prize. Take a few examples which I observed at their autumn show. For the best six stove and greenhouse plants A was first and third, B second. C and D, finding no chance of a place there, set their plants up as six miscellaneous plants. B now had first place, A second, and either C or D again thrown out of a place. Here you see A had three stands suitable for entering for the premier prizes, and had not an opponent turned up with a stand which was certain to throw him out of one of the three prizes he would have set up three stands and won first, second, and

third. A grows Heaths well and shows them well, he consequently had first and second unopposed, everyone else being driven out of the field. Another instance: I observed E had first, second, third, and fourth for twelve Carnations, the same exhibitor having the same number of prizes for six Carnations. F came off with first, second, third, and fourth for twelve Picotees, and also for six of the same. No opposition was offered to either of these, their claims to the prizes being quite established, and apparently quietly arranged between themselves.

I do not think it is right for a Society supported by public money to thus give large growers the opportunity of monopolising the whole of the prizes offered for certain articles. The original object of flower shows was to encourage small growers, then general good cultivators. This Society, I contend, does not do so; it is an unequal contest. Large growers should be content with first place, and small growers will be content to come behind them. The Newcastle Society ought to wipe this blot out of their book now that they are in prosperity. "Oh!" say they, "we could not get a show otherwise." How do other societies do? say I. Most societies have a rule as follows:—"No competitor allowed to stage more than one lot for any one prize." I contend that this rule should not be omitted by any society in the country.

I was much pleased with many things which I saw at the Newcastle autumn show. I was pleased to see the plants arranged in a manner that the public could see them on all sides. I was pleased to see such grand stands of Dahlias, Gladioli, Asters, &c. The dinner-table decorations were attractive, as were also the plants staged for table decoration, but the effect was spoiled by their being packed too closely together, and I am glad to see that we are likely to have similar treats at the forthcoming shows at Newcastle.

I am not a disappointed exhibitor, and I hope Mr. Taylor will not take any adverse criticism which I may have made as being prompted by any other wish than to see this and all similar societies healthy and prosperous.—R. INGLIS.

#### MADRESFIELD COURT GRAPE.

THIS Grape—like many others—is getting uncommonly ill spoken of by some, and just as well spoken of by others. It would appear, however, that all are agreed as to its having some grand points, such as its free-bearing qualities, its immense berries, and good flavour. These are certainly fine characteristics, and if it could be produced as perfectly swelled and coloured, and kept afterwards as Mr. Johnston showed it at Dundee last September, where is the cultivator that would not like to grow it? But the great defect which it develops in not a few instances is, that almost every berry splits after becoming fully ripe, or just as it attains perfection. Mr. Hunter at Lambton Castle had this year the most extraordinary bunch of it that was ever produced perhaps, and he intended to show it at Dundee, but it cracked, so that it was not fit to show in September. The question becomes one of importance, Is this grand Grape, or this Grape with so many grand points, to be condemned and abandoned because, under certain circumstances, it develops this certainly fatal flaw or fault? That it does remarkably well under some conditions is unquestionable. At Bolton Hall in Yorkshire it invariably does well, and never cracks. It is said by Mr. Roberts, the gardener at Bolton Hall, that it succeeds even better in the same house than Lady Downe's, Alicante, and Barbarossa. It of course becomes a question as to the exact conditions under which this, or any other Grape which often fails, succeeds so perfectly. It is said to be growing in a border which is all inside the vinery, and composed of loam of the carboniferous limestone, bones, brick-rubbish, and a good deal of charred garden rubbish. These are just the conditions under which a Grape subject to split would be expected to be most free from this fault, and it is found so. It is not a very uncommon thing to see even Black Hamburgs split to some extent when a very wet time succeeds a dry season, when the roots are in outside borders in wet localities. The amount of water in an inside border is entirely under control; and, moreover, when the border is made up of such open material as the inside border at Bolton Hall, the amount of water held in suspension is reduced to a minimum, and consequently the chances of this or any Grape splitting. The particulars regarding the prominent development of this flaw in the case of the grand bunch at Lambton would be interesting. According to Mr. Hunter's own account of his practice, enormous supplies of water are one of the chief

features of it. There are few Grapes, even our oldest standards, but what require some special points of culture. The Muscat, to do it well, requires strong heat, bright light, and very generous treatment. The Black Hamburg succeeds fairly if it gets very ordinary treatment, but it never colours so well in the heat required to finish Muscats as it does in a cooler house. Lady Downe's—our best keeping Grape—will be and is often ruined by too much heat at the stoning period; and so I might refer to all other Grapes, scarcely one of which but requires some special guarding at certain stages of their growth. But who would think of rushing into print to condemn these Grapes? Whoever did so would be thought to be most successful in revealing his own ignorance.

Would it not be worth while, in gardens where space could be afforded to carry out such an arrangement, to set apart a house with its border all inside, for such a noble Grape as Madresfield Court assuredly is—all but its tendency to split—and subject it to special treatment for this evil? and it might also be worth while to associate with it that other well-abused Grape, Golden Champion. The same treatment would prevent it from splitting and spotting that would prevent the first of those evils in Madresfield Court. And I never heard of these two Grapes being placed on the table in good condition yet, that they did not alike meet with the most unreserved praise as being two grand Grapes. It is well known to experienced Grape-growers that an over-damp atmosphere will cause most Grapes to spot; and this year I saw a striking example of this in the case of Gros Colman, the Duke of Buccleuch, and slightly in Black Hamburgs, all in the same house, through oversprinkling of the floor of the vinery in dull weather when little air could be given. Would it be reasonable to condemn these three Grapes on this account? It is quite right that all new things should be well criticised, but it is to be feared that much of the criticism in this age of scribbling is advanced for the mere sake of finding fault, instead of bringing out the special conditions under which fine sorts do well.—PRACTITIONER (in *The Gardener*.)

#### LAURUSTINUSES FOR INDOOR DECORATION IN WINTER.

THIS is a useful winter-flowering shrub which seems to have been overlooked by many who have to keep greenhouses and conservatories gay at this season of the year. I saw some well-grown Laurustinuses a week or so ago at Thoresby Park, and amongst the many attractive plants there these shrubs were very conspicuous. They were grown in large tubs, and Mr. Henderson said they had stood in the open air all summer up to October. They are removed outside again in spring, and their cultivation is extremely simple. They have been grown indoors in the winter time for a number of years at Thoresby, and the flowers open much freer under glass than in the open air. At the time of my visit the plants were a complete mass of purple with the opening buds, and by this time they will be a perfect sheet of pure white, and the Ixora-like trusses of flowers are not only ornamental on the plants, but they are extremely useful in a cut state. Smaller plants than those at Thoresby might, no doubt, be had with a proportionate quantity of flowers, and they would be exceedingly useful in mixing with other flowering subjects on conservatory stages.—S. W.

#### THE NURSERIES OF MESSRS. W. CUTBUSH AND SON, BARNET AND HIGHGATE.

SINCE the lamented death of Mr. William Cutbush in May last the Barnet Nurseries have become allied with those of Highgate, and both are now conducted by the firm above named as the only horticultural representatives of an old horticultural family. Mr. William Cutbush commenced business at Barnet thirty-six years ago, and throughout that time was esteemed for his honourable dealings, high character, and business assiduity. Mr. James Cutbush, inheriting the family "roof tree," has continued residing at Highgate, and has conducted that nursery, also another branch at Finchley, in a practical and exemplary manner.

These nurseries are not large, yet the trio may amount in area to about thirty acres. Geographically they occupy a high position, perhaps the highest of any metropolitan nurseries of note. From Highgate the "modern Babylon" is overlooked, but is seen only through a veil of misty smoke by

day, and at night resembles a panorama—a topsy-turvy firmament—of lamps. The air of the standpoint is clear and bracing, for it floats above the level of the mist and the line of the smoke. Finchley is even higher than Highgate, and higher still than Finchley is Barnet, and at the highest part of Barnet on the plateau of its hill are the nurseries: the nurseries of Messrs. Cutbush & Sons, therefore, occupy a “high position.”

The two nurseries, Highgate and Barnet, are connected by a loop of the Great Northern Railway, Finchley being midway between the two places. The country traversed is pleasant, even picturesque, for the ground is boldly undulated, and if the trees are not of the largest the grass is of the greenest. It is a district of pasture lands and meadows, unbroken as yet by the “civilising influences of the plough,” and uninvaded by the ever-spreading, ever-rising “monuments of art”—dwellings of bricks and mortar. Why does the city linger so long in travelling southwards? and why does the country begin so suddenly northwards? The answer is found in two short but potent words—gravel, clay. Southwards the former attracts and man rears his dwellings; northwards the latter repels and nature reigns supreme.

Yet before reaching the nurseries at Barnet at least one object of art attracts—the noble parish church, one of the many edifices which adorn our land, and more than any other link the past with the present, and also which happily will connect the present with the future, for this is a generation of church restoration, and the fine edifice at Barnet has been restored at a cost of £12,000. It is built of flints with dressings of stone, and is of imposing appearance, a structure which any town might be proud of owning.

But we are at the nurseries, and here we find, like many other eminences in clay districts, that the soil is light—an admixture of sand and gravel, the valleys only being of clay. On this bleak exposure the air is keen and clear, just such where the Heather thrives, and doubtless the situation and the nature of the water have much to do with the healthy freedom with which hardwooded plants grow in this nursery. For years it has been noted for the production of *Ericas*, *Epacris*, &c., and only recently thirty thousand plants of this nature have been sold from its stores, and there are thousands more in various stages of growth preparing to meet future demands.

A visit on the heels of a “clearing-out,” and when alterations such as placing new heating apparatus in the houses, is not a time to find a nursery in showy trimness. Beyond this it perhaps betrays a suspicion of the absence of a “master’s eye.” Failing health and death ever leaves marks more or less melancholy behind. But a master’s eye and energy is again visible, and Barnet may be expected in due time to reflect the order, neatness, and superior condition of Highgate. At Barnet there are several glass structures—large light houses, which after the sale one might have expected to have found nearly empty, yet they are more nearly full, some even being crowded. In the propagating house in a flourishing state is a fine lot of *Camellias* grafted six weeks ago, and nearly every one “taken.” Many thousands of *Camellia* cuttings for stocks are also as healthy as could be desired. *Epiphyllums* are being extensively increased by grafting them on *Pereskia* stocks, and this work is skilfully done, the union of stock and graft being nearly imperceptible. *Boronia*s, especially *B. pinnata*, also *Acacias*, *Ericas*, *Dracophyllums*, &c., are being provided for future demands by the skilful propagator. In other houses plants of this nature are in various stages of growth, from small portable “market stuff” to three-quarter and half specimens. *Genetyllises* are growing with the freedom of *Privet*, *Phenocomas*, *Correas* (*magnifica* and *cardinalis*) are equally healthy; and *Gompholobium*s, *Pleromas*, *Polygalas*, *Aphelexes*, *Eriostemons*, *Daphnes*, &c., are luxuriating in the several structures; about half a score of large houses are devoted to plants of this nature. A large span-roofed house about 100 feet in length is filled with large and small *Camellias*, heavily-berried *Aucubas* (*A. japonica vera*), *Acacias* (*armata*, *Riceana*, &c.); choice *Rhododendrons*, and a goodly number of *Statices profusa*. *Stove* plants are also grown—popular kinds for decorative purposes, such as *Dracenas*, *Encharises*, *Ardisia crenulata*, a remarkably fine stock; *Stephanotes*, and the fine climber *Ipomœa Horsfallii*. Besides the houses are extensive ranges of pits. In one range are 20,000 *Ericas* and *Epacris* for flowering next year, and in others are plants in an advanced stage for decorative purposes, such as *Ericas cafra*, *hyemalis*, *colorans*, &c., flowering profusely, and in excellent condition. Plants of this nature are indispensable for winter decoration, and the way in which

they are grown in this and other nurseries where special attention is given to them insures a supply of plants much better, also more cheaply, provided than can be produced by gardeners who have so many and varied demands on their time and attention.

In the grounds are many *Conifers*, &c. *Araucarias* in this high bleak exposure having passed uninjured through many winters, and are now commanding specimens. Standard variegated *Hollies* are numerous and fine, and there are good stocks of *Deodars*, *Ivies*, &c., and *Vines* in pots. About a quarter of a mile distant is another nursery worthy of a visit if only to inspect the extensive and splendid collection of *Hollies*. The green-leaved varieties are numerous, but the best of the variegated sorts surpass them in numbers and effect. The *Golden* and *Silver Queens*, *marginata*, and others are in thousands, the shrubs ranging from 3 to 6 feet in height. They are in the most perfect health and colour, and are adaptable more than any other shrub in cultivation to brighten and cheer on lawns and in pleasure grounds throughout the dull months of winter. *Rhododendrons* thrive admirably in the gravelly but peatless soil of this nursery, as do hardy Ghent *Azaleas*, *A. sinensis*. There are also evergreens and *Conifers* and *Ivies*; many thousands of the common green *Ivy* in pots for insuring safe removal. There are also forest trees and fruit trees; but the latter, with *Roses*, are chiefly grown at Finchley, where the soil and situation are specially favourable for their free yet robust and hardy growth. The Barnet Nursery is an important addition to business of the firm under whose personal supervision it will shortly again be brought into systematic order.

HIGHGATE.—This nursery is in an admirable state, the plants in the houses and the shrubs, &c., in the grounds being alike creditable to their owner and his foremen. The span-roofed show house, about 50 feet by 30, is filled with clean and healthy *Palms*, *Ferns*, *Yuccas*, and *Dracenas*, and the foliage is enlivened by flowering plants of *Epiphyllums*. A few of the best of these valuable winter-decorative plants are *violacea grandiflora*, purple white tube, free; *Salmonæa*, rosy salmon; *tricolor*, purple and scarlet, fine; *Morrelliana*, scarlet; *Snowii*, purplish red; and *amabilis*, deep rose. Two other houses are filled with *Erica Willmoreana*, the plants being in the finest possible condition; and equally superior are the *Epacris*, which occupied an adjoining structure, the foliage being of the deepest green, and the shoots of 2 to 3 feet in length closely set with flower buds. A few of the most useful are the following:—*Vesta*, *Viscountess Hill*, *Lady Panmure*, *The Bride*, *alba odorata*, and *hyacinthiflora rosea* amongst the early-flowering; *Walkerii*, *rubella*, *fulgens*, *Fairburniana*, *hyacinthiflora candidissima*, and *courasensis* being good as later-flowering sorts. Another house is filled with *Azaleas*, half-specimens, and the next with small plants of the best continental varieties. A fine stock of *Bossia Hendersonii*, a valuable greenhouse plant, is noticeable, as also are young plants of *Witsenia corymbosa*, a good old Cape plant, distinct in habit and attractive by its purplish blue flowers. Of *Camellias* there is an excellent collection including many well-furnished plants of the old *alba plena*, the most useful *Camellia* in cultivation. The plants of this are numerous and superior, and are well set with flower buds. The plants of the different varieties range in height from 5 inches to 5 feet. Amongst them are interspersed *Chrysanthemums*, the plants having been grown this year in a natural manner. On the shelves of this and adjoining house is an extensive stock of double *Primulas*, than which no plants in the winter are more valuable for furnishing pure white flowers for bouquets, &c. Brick pits are crowded with *Heaths* for the next year’s supply—a most promising stock, and successive batches are struck and striking in the propagating house; and *Hyacinths*, for which this nursery is famed, are snugly buried in cocoa-nut fibre refuse, the greater number being in the open air, only a few for early flowering being buried under glass.

The outdoor department is fully as worthy of inspection as the stock of plants in the houses. *Euonymuses*, *Retinosporas*, &c., are attractively disposed, and *Bays*, *Laurostimus*, &c., in pots are numerous and good. Standard *Bays* are grown here equal in the straightness of their stems and the symmetry of their heads to the continental specimens, and these shrubs are never injured by frost at Highgate. There are huge bushes of *Bays*, also a hedge of them, than which nothing in their way could look better. *Laurels* are, too, very conspicuous, not wildly growing untended shrubs of the common variety, but handsome specimens of those noble sorts—

rotundifolia, colehica, and caucasica. These are handsome pyramids 6 to 8 feet high, and have been carefully pinched and tended. For lawns and prominent places in shrubberies such specimens as these are highly ornamental. Arbutuses are largely grown, and thrive admirably; and of Ivies many thousands are grown in pots ready for removal at any season. Evergreen Oaks are similarly grown, and the pots plunged in the soil. This is done to ensure the safe removal of specimens which otherwise would not succeed, these being the most "ticklish" to transplant of all evergreens. The specimens thus grown are, like the Laurels, large and well furnished. There are ornamental-flowering and drooping deciduous trees; also Conifers, Yuccas, and other subjects completing the stock of this well managed and favourably and pleasantly situated nursery.

In extent it is small, but a wide trade connection is associated with it, and its business tone is manifestly brisk and healthy. Neither is it likely to show any abatement so long as the experienced head continues to direct in the prompt and able manner which has won for him the confidence of many friends and supporters, metropolitan and provincial.—VISITOR.

## ROYAL HORTICULTURAL SOCIETY.

DECEMBER 6TH.

FRUIT COMMITTEE.—Henry Webb, Esq., V.P. in the chair. Mr. Bland, of Fordham near Soham, sent a seedling Apple of good quality, but not of greater merit than many others in cultivation. Messrs. Merryweather & Son of Southwell sent a new kitchen Apple called Bramley's Seedling, of large size and excellent quality. It was highly commended. Mr. P. Grieve, Culford Gardens, Bury St. Edmunds, sent a seedling Pear which was not of sufficient merit to receive a certificate. Rev. A. Rawson, The Vicarage, Bromley, Kent, sent a seedling Pear, raised by crossing Seckle and Forelle. It is of the form of Figue de Naples, and has a yellowish flesh of delicious flavour similar to that of Seckle. The fruit was rather decayed, but was thought so good the Committee desired to see it again. D. P. Bell, Esq., Clive House, Alnwick, sent a bunch of a seedling Grape with the following communication:—"The Vine was raised a few years ago, and is a cross with Black Morocco, and a seedling raised, I understand, at Wortley. It is a free grower, a heavy cropper, and has a strong constitution. It is not liable to shank, nor the berries to scald as Lady Downe's does, its keeping properties are quite equal to Lady Downe's, and its colour uniformly better. Since the Vines were planted six years ago it has been excessively cropped until this year, but it has never failed to colour its fruit as well as the specimen now shown."

The bunch is large and heavily shouldered with a stout stalk. The berry stalks are stout, and the berries large and roundish oval, frequently with sutural furrows. Skin quite black and membranous, covered with a fine bloom. Flesh firm, tender, very juicy, and sweet. It was unanimously awarded a first-class certificate. This is a far superior fruit to Alicante, and will no doubt prove to be a late-keeping variety of great value.

Mr. Bennett, Rabley, sent a brace of Rabley Cucumbers, Tomatoes, and Strawberries. Mr. Ollerhead, gardener to Sir H. Peek, Bart., Wimbledon House, sent two fine Shaddocks, and was awarded a letter of thanks. Mr. Miles, of Wycombe Abbey Gardens, brought a Pine Apple of conical shape like the Enville, of tender flesh and delicious flavour, which was much admired, and a vote of thanks was awarded to Mr. Miles, who promised to bring another fruit, and to furnish full particulars respecting it. Henry Webb, Esq., of Redstone Manor House, Redhill, sent dishes of Glou Morveau and Vicar of Winkfield Pears. The former was of excellent flavour. Also a dish of Passe Colmar. A vote of thanks was awarded.

FLORAL COMMITTEE.—W. B. Kellock, Esq., in the chair. This was the closing meeting of the year—the last of a series of horticultural gatherings of the greatest importance in the advancement of the art which they were instituted to foster. Nearly all the meetings of the year have been good meetings—many of them excellent, both as regards the subjects exhibited and the assemblages of horticulturists. This was also a successful meeting. The magnificent group of Orchids exhibited by Sir Trevor Laurence, Bart., M.P., Burford Lodge, Dorking, was alone worth a journey of a hundred miles to see. The collection consisted of about thirty plants in various sizes. A noble plant of *Zygopetalum Mackayi* was 4 feet in diameter, and had twenty robust spikes; *Calanthe Veitchii* was in such condition both for vigour of spikes and the rich colour of the flowers that we have seldom seen equalled and never surpassed; *Odontoglossum Insleyi leopardinum* had twelve spikes; and *Cypripedium insigne*, a grand variety, was 3 feet in diameter. *Dendrobium primulinum giganteum* was very conspicuous; the two stems were covered with flowers from the root to their tips, the plant having forty flowers. *Epidendrum vitellinum majus*, *Odontoglossum cordatum superbum*, *O. Pescatorei*, *O. constrictum*,

*O. gloriosum*, *O. roseum*, with *Masdevallias*, *Sophranitis*, very superior; *Tricopilias*, and the curious *Restrepia antennifera* completed this remarkably fine collection. The plants were grown by Mr. Spyers.

Messrs. Veitch & Sons, the Royal Exotic Nursery, Chelsea, also exhibited about thirty plants of Orchids, alike interesting and beautiful. A conspicuous plant of *Laelia anceps* occupied the centre of the group. *Laelia albidia* in two varieties was very lovely. *Cypripediums*—*Sedeni insigne*, *Maulei*, very fine; *Harrisianum*, *Crossianum*, and *Schlimmii album* were in great beauty. Amongst the smaller plants were the striking *Odontoglossum cirrosum*, also *O. Rossi majus*, and *O. nevadense*. Amongst the *Masdevallias* were *Barlaana Tovarensis*, *ignea rubescens*, &c. *Lycaste Skinneri alba* was very pure. These with others formed a group which deservedly attracted great attention, and for which a vote of thanks was awarded. Messrs. Veitch also exhibited *Poinsettia pulcherrima amena* altogether softer in colour than the species, the bracts being also broader, more regular, and more closely arranged. The heads were about a foot in diameter.

Mr. Denning, gardener to Lord Londesborough, Londesborough Lodge, Norbiton, exhibited *Oncidium Londesboroughianum*, a splendid flower with a broad lip of the brightest yellow, and broad and stout richly marked petals and sepals, which add greatly to the beauty of the flower. The long arching spike had ten expanded flowers, and as many more to open. It is a most distinct and valuable addition to the family, and worthy of bearing so good a name. A first-class certificate was unanimously awarded.

A box of twenty-four varieties of cut blooms of zonal Geraniums was sent by Mr. Cannell, Swanley Nurseries, Kent, which for size, substance, and brightness of colours have not been surpassed at any summer show. The varieties were Rev. J. Atkinson, Eros, Circulator, Alice Spencer, Alonzo, Sir C. Campbell, Heartsease, Havelock, A. Henderson, Sybil Holden, New Life, Peabody, Jealousy, Sir G. Wolseley, Imogene, White Clipper, Mabel Eden, Astarte, Marguerite Ponton, Dr. Sharpe, De Lesseps, Mr. J. F. Fenn, and Vanessa—a brilliant display, and which merited the vote of thanks awarded.

Mr. Mann, the Nursery, Brentwood, exhibited plants of zonal Geranium Earl of Beaconsfield, a dwarf and very profuse-flowering variety, a little brighter and larger in flower than *Vesuvius*.

Mr. Ollerhead, gardener to Sir W. Peek, Bart., Wimbledon House, exhibited plants of *Plumbago rosea*, which had been struck from cuttings in the spring, and the plants trained on the back wall of a Melon house. The plants were in 8-inch pots, they were 7 feet high and 3 feet in diameter, and were covered in every part with fine spikes of lovely-coloured flowers. Mr. Ollerhead also exhibited shoots 6 feet high surmounted with flowers of *Euphorbia jacquiniiflora*, from plants planted in a Pine pit. They were exceedingly vigorous; and Mr. Parker, Exotic Nursery, Tooting, exhibited cut blooms of the sweet and charming aquatic *Aponogeton distachyon*, which had been grown in the open water; also flowering plants of *Iberis semperflorens* and *Streptocarpus Greenii* delicate.

A remarkable collection of pressed Fern fronds and autumn leaves was exhibited by Mr. Howard, 29, King Street, Covent Garden. Many of the specimens were pressed last year; the colours were admirably preserved. They had been prepared in America by Mrs. Reed Watson, East Windsor Hill, Conn. A vote of thanks was awarded for them.

## DIOSPYROS KAKI.

My friend Dr. Voelcker has been kind enough to have the fruit of the *Diospyros Kaki* analysed in his laboratory. The quantity of tannic acid it is shown to contain is quite sufficient to account for the wry faces of those who first tasted it. Let us hope, as is probably the case, that other varieties contain more sugar and less of the astringent principle.

Water .....	84.64
Albuminous compounds (containing nitrogen) .....	0.62
Crude woody fibre .....	2.11
Tannic acid .....	2.32
Sugar, pecten, &c. ....	9.59
Mineral matter (ash) .....	0.42

100.00

—G. F. WILSON.

## CAPE PELARGONIUMS.

I WANT to establish a good collection of this beautiful tribe of plants, perhaps some of the contributors of the Journal can assist me in doing so. I have some—namely, *ardens*, *echinatum*, *filipendulifolium*, *flexuosum*, *gibbosum*, *macrorhizon*, *quinquevulnerum*, *reniforme*, *semperflorens*, and *tetragonum*. These were all I could obtain of a nurseryman in

my neighbourhood, but I think there must be many others, unless these "plants of the past" are become nearly extinct. I remember some years ago seeing a work, but I do not recollect the name of the author, in which Cape Geraniums were represented by some very good illustrations. The flowers figured were grotesque, curious, and many of them beautiful. I desire names in addition to those above given, and to know where the plants can be obtained.—CAPE.

### THE COST AND ADVANTAGES OF DEEP CULTIVATION.

FINDING my present garden too limited in extent, I have this autumn hired an additional plot of 600 square yards. This piece of land comprises one of twelve allotment gardens, and has been cropped for the last twenty years or more chiefly with Potatoes. Along with the annual crop of Potatoes the land has produced a fair crop of weeds; as many of these weeds were deep-rooted (the land only being cultivated at a maximum depth of 6 inches), I at once determined to subsoil or double-dig it over.

Having now done so it has occurred to me that my experience as to the cost of the work might be useful to some readers; I submit also my estimate of the advantages of deep digging.

I found that myself and a labourer working cheerfully could subsoil or double-dig about 100 square yards of land in eight hours. If we charge labour at the moderate rate of 3*d.* per hour, the cost will amount to  $\frac{1}{2}$ *d.* per yard, or say at the rate of £10 per acre. In some portions of the plot the cost was nearly double, owing to beds of deep-rooted weeds, including Thistles, Docks and Bindweed. These roots were all picked out, and the bottom spit dug twice over; but where the land was fairly clear of weeds the above is a fair estimate of the time and labour required.

I find the four or five-tined steel digging-fork far better for the work than the spade; in fact a man using a spade would not do the work so well, nor would he be able to do as much of it. To ensure the work being done thoroughly, a master or some trustworthy person should be there to take a part in the work. It is work that is easy to slip, leaving a portion of the bottom soil undug, and the weed roots unpicked out. The total depth of the two spits would be from 15 to 18 inches. So much as to the labour and cost, and now as to the advantages.

In the first place it should be remembered that subsoiling and trenching are quite distinct. I can quite understand why some persons object to trenching. I have seen land trenched and made so barren by the operation that even weeds have refused to grow on it for a season. I never trench land before it has been subsoiled two or three seasons previously, for I have found from experience that bringing the raw and hungry subsoil to the surface and burying the top soil is a great mistake.

The first advantage arising from deep digging is the removal of deep-rooted weeds. It certainly is a great advantage to the gardener to be able to determine beforehand what class of plants he will grow on a given piece of land, and deep-rooted weeds can only be destroyed by deep digging. But if I may be allowed to digress, let me here state that I think "weeds" are often abused and called by harder names than they deserve. It seems to me like "man's ingratitude" and "benefits forgot" for the gardener to complain in such bitter language about the "growth of evil weeds," for his soil owes much of its fertility to the accumulated deposit of ages of weed remains. For my part I have long looked upon weeds as "friends in disguise." But however slow many of us may be to find out the uses and value of weeds, I think we are all agreed that it is not convenient to grow them indiscriminately amongst our garden crops, and by far the best and cheapest plan to eradicate those having deep roots is to subsoil and pick them out by hand.

Another great advantage of deep cultivation in my opinion is this—land that is thoroughly cultivated has not only greater power of retaining moisture after rain, but it is enabled to gather a supply of moisture during periods of severe drought: from the soil beneath and from the atmosphere above moisture may be obtained. Use the fork or spade in the autumn and the hoe freely during the summer, and the crops will not often suffer from dry weather.

To use the watering can during every fit of dry weather is a mischievous practice, for it is more likely to ruin the crop than to benefit it. If you wish to destroy the independence of a plant, if you wish to pauperise it, if you wish the sun to burn it up, by all means fly to the watering can; but if you

wish your crop to be independent of the season, if you wish it to enjoy the bright warm sunshine of summer—in a word, if you wish your crop to come to perfection, dig deep and hoe oft (once a-week if you like), and neither weeds nor dry weather will hurt your crop. The large amount of moisture in the atmosphere during the hot and dry weather of summer may be taken advantage of. The soil may be prepared by thorough cultivation to act as a powerful condenser; and if we thus offer facilities for the circulation of the air in the soil we not only gather a supply of moisture to sustain the plants in health during the summer, but all through the wet and cold days of winter a good work is still going on.

The exposure of the soil by deep digging to the disintegrating influences of the rains and frosts of winter has a very beneficial result on nearly all classes of soils. We thus assist Nature (ever ready to help us) to unlock the latent stores of plant food of which the crust of the earth is composed. The soil is rich in mineral food, but without cultivation and exposure to the air it remains insoluble, and is not available as food for plants. Gardeners would do well to remember that cultivation of the soil is an equivalent for manuring it.

I think it is about time I was bringing my writing to a close, as too much writing at once is as bad as too much digging, so I will just mention one other advantage and then conclude. Most of us are aware that pulverised soil moderately dry is a powerful deodoriser, and very possibly, as the air circulates through the soil, it may be purified and the soil enriched to their mutual advantage. The poisonous gases floating in the air are absorbed and captured by the soil as they pass over its surface. The soil having once obtained possession of them transmutes them into food for plants.—W. LOVEL, *Weaverthorpe, York.*

### CHAPTERS ON INSECTS FOR GARDENERS.

No. 14.

IN the course of our survey of the domains of insect life we have now arrived at an order which wins admirers even amongst those who have little taste for, or knowledge of, natural history. One section of this order—the butterflies—are associated in the case of a number of persons with the earliest recollections of childhood and of the pleasures of country scenery. If we were to ask the poet or the artist to assign these and the equally gaudy moths a fitting place in the ranks of insects, it is probable they would at once declare that these delicately plumed and variously coloured creatures ought to form the leading or principal group. Pursuing, however, that natural arrangement which has the approval of most entomologists, and working as before from the lower to the higher, we step from the frequently uninviting insects of the order Hemiptera to the Lepidoptera, which embraces the butterflies and moths. Beyond this lies the Hymenopterous order, so that our friends the bees and our enemies the wasps and sawflies might consider themselves (could they reason on the subject) superior to their broad-winged downy-coated relatives, which possess the same number of the organs of flight. For many reasons the Lepidoptera have had more attention given to them by the entomologist than any other order of insects. Their conspicuousness on the wing, the elegance or beauty of their appearance, the comparative ease with which they can be kept in cabinets and the regularity of their transformations, with the facilities for watching these usually attainable—all these circumstances have given butterflies and moths a position of their own amongst the insect tribes. It is amusing to find that not a few individuals have prided themselves on being "entomologists," whose knowledge of insects goes hardly beyond the Lepidoptera, and who could scarcely say whether the grub of a beetle has legs or not, or give any account of the habits of a dragon fly. This is much as if a man professed to be an ornithologist who only collected water-fowl or finches. Happily for science a better state of things has begun, and many gardeners are becoming well acquainted with the structure and habits of insects.

Looking at the order Lepidoptera from the horticultural point of view, we perceive that it occupies a middle place. On æsthetic grounds we might praise it, for it includes species that give ornament to the garden or the parterre in their winged condition; but also, unfortunately, various species in their caterpillar state are more or less harmful to vegetation. Of friends to the gardener we can reckon few amongst butterflies and moths, for the larvae of these are not parasitic in habit, though one singular exception occurs abroad, where the larva

of a small moth has been discovered living in the manner of a parasite on a species of Lantern-fly. There are, however, some caterpillars which subsist partially on the carcases of their lesser brethren, and two noteworthy instances are the Satellite (*Scopelosoma satellitia*) and the Dun Bar (*Cosmia trapezina*); they are not at present sufficiently common to be of marked utility. Certain of the diminutive moths in the genus *Pinea* also deposit eggs in such situations that their larvæ are able to prey upon the pupæ of Lepidoptera. And this is pretty nearly all we can say; for though the crushed bodies of caterpillars have been made to yield a dye, and other species are, as is well known, valuable as silk-producers, for neither of these circumstances have they special claim on the horticulturist's regard.

The transformations undergone by these insects, taken as a whole, are now too familiar to all intelligent persons to require a detailed account in this place of the successive stages of egg, larva, and pupa or chrysalis, from which the imago, or mature insect, is finally produced. As in every order, the general rules are subject to some curious exceptions or variations; but these are invariable—namely, that every butterfly or moth goes through the four stages—long or short, and that the number of legs in the larva are six, and of claspers or pro-legs never more than ten nor less than four. The body, usually cylindrical, is made up of twelve segments, the head being furnished with simple eyes or ocelli, short palpi or feelers, and a pair of jaws capable of biting very effectively. The food of larvæ in the order is vegetable only; and though they are not among the most injurious of insects, their ravages are often peculiarly noticeable, because they take in a large amount of sustenance, often in a short space of time, and also sometimes assemble in companies. The pupa of a butterfly or moth—whether it be simply suspended, laid upon or buried in the earth, or enclosed in a cocoon—has no distinction of parts; though it may be angulated or variously shaped, yet the outline of the future insect may be traced upon its surface in many instances. Whether the pupa state lasts for weeks or months, it is always a period of inactivity; the pupa neither eats nor moves—except an occasional twirl, perhaps, when subjected to any annoyance—till the time comes for the extrication of the imago; and in some species the moth has no small difficulty in disengaging itself from a small or hard cocoon, Nature aiding its strength and ingenuity sometimes by supplying a solvent fluid.

But, taking as a specimen for investigation either a butterfly or moth, since it is mainly on the perfect insect that we rest our definition of the orders, we observe first that the antennæ are either clubbed as in the butterflies, spindle-shaped as in the hawk moths, or feathered or thread-like as in the bulk of the moths. Secondly, the four wings, rarely absent, are, save in a few species with clear and membranous wings, covered with scales (popularly called feathers, really somewhat akin to hairs), which by a very moderate magnifier we can see are rooted in the wing and arranged in tile fashion. Thirdly, the head is furnished with compound hairy eyes, and the organs of the mouth take the form of a proboscis or sucker. Fourthly, the thorax is stout and muscular, because on it depend the movements of the wings and legs; the abdomen, though flexible and usually oval, having little of the power we find that portion of the body possesses in some of the orders. Both thorax and abdomen are downy. Fifthly, the legs are hairy and furnished with two claws, in number six; the front pair abortive in several species of the butterflies. And a passing explanation as to three or four English words associated with the Lepidoptera is desirable. First with regard to the oft-used word "butterfly." This has lately been discussed in "Notes and Queries," and several suggestions thrown out why "butter" might form part of the name of these aerial creatures. It may have been because our forefathers noticed them as abundant during what is called the "butter" season, or because their wings were of the colour of butter, as in some common species; or because, so thinks one author, they were believed to represent evil spirits, who came in that guise and bewitched the butter! All these are rather lame theories, and two suppositions are more probable—either that the old name was "budder-fly," a fly that buds or bursts forth from a pupa case which looks inanimate; or else that the name arose from the Saxon word *bodda*, applied to a grub or crawling creature, and still existing in the term "bots," well known to rearsers of horses. The butterfly, then, would mean simply the fly which comes from the grub, and dim notions about the transformations of insects certainly were of early date in history. The word "moth" presents this

peculiarity, that it doubtless took its origin from the habits of those small species which for thousands of years have been noticed to infest and destroy woollen and other materials, and by degrees it spread upwards till it was used to cover the whole of the second great division of the Lepidoptera. The root is an old word to be traced in many languages, meaning something that eats or chews, therefore quite inapplicable to all these insects in their winged state. Then there is "caterpillar," the first half of which word must be left in obscurity, the second clearly applying to the action of these creatures in "pilling," peeling, or stripping plants and trees. Of "chrysalis," still used by a number of authors to express the third stage of insect life, one can only say that it would be better to supplant it by the word "pupa," as "chrysalis" originally meant those pupæ which have a lustrous or golden appearance, as in a few butterflies.

The statement has been freely copied by compilers of books that you may at once tell a butterfly from a moth by the knobbed antennæ of the former; but this is not very reliable, since in the Red-horns, and in some of the Blues, the clubbing is not very marked. More fallacious still is the popular supposition that moths are dull-coloured and butterflies gaily adorned, for there are many examples to the contrary, though it is possible to refer to whole groups of moths where sombre tints predominate. The majority of our butterflies are also lively in colouring, though they cannot compete with the brilliancy of exotic species. A good distinction is the position in which the wings are placed when the insect is at rest. Our butterflies when sitting on a flower or leaf generally bring all the wings together above the back, so that all that is seen is the under side of the hind wings. The frisky little fellows we call Skippers practise, however, an eccentricity, for they often raise the fore wings and drop the hinder pair horizontally. Most moths, on the other hand, either spread out all the wings flat, or they fold up the hind wings, and hide these and the body by sloping over them the fore wings. In the majority of moths we find a singular formation, called the "spring and socket arrangement." A curved bristle at the base of the hind wings passes into a small loop of membrane or hairs, and works up and down when the insect is on the wing, possibly needless in the case of butterflies, which have much less weight to carry usually. "But, don't butterflies fly by day and moths by night?" says someone. Well, we are tolerably safe in asserting butterflies fly by day, though an occasional White or Red Admiral has been seen careering about at even tide, experimenting on the quality of the honey to be found at that time; but this is no adequate distinction between the two groups. There are moths the regular habit of which is to fly in the bright sunshine; there are some that prefer dull days, and some also that now and then make day excursions, though it is their general habit to take wing at or about dusk; and of the night-flying moths there is a proportion fond of the twilight rather than of those hours when "gloom o'erspreads the sky."

The number of our British butterflies, including even a couple of somewhat doubtful residents, is only sixty-six, a proportion so remarkably small as compared with the sum total of our moths, that a variety of explanations have been given, none of them satisfactory. Perhaps the likeliest is that which attributes it to the variableness of our climate and the dampness of our average winters. Against these insects, taken as a whole, the horticulturist cannot bring a heavy indictment, since his enemies are confined to a few species, though these are certainly apt in some years to occasion him annoyance. But butterflies do not attack any plants of special value, such as the Vine amongst fruits, or the Potato amongst vegetables, or the Rose amongst flowers. Naturally, many butterflies are attracted to gardens by the flowers they display, travelling at times long distances for this purpose, though some of our species never quit the marsh, the field, or the wood where they have been bred.—J. R. S. C.

### VICTORIA PARK.

The ground was purchased with the money paid by the Duke of Sutherland to the Government for Stafford House, £72,000. The area of the park is about 290 acres. It is surrounded by an industrial population with but little leisure time for pleasure, and living for the most part in crowded workrooms and ill-ventilated dwellings. Such people know best how to appreciate the contrast between their usual surroundings and the beauties of Nature when a little leisure gives them an opportunity

The pure air, green grass, trees, shrubs, and bright flowers are nowhere more prized than at the East End. Bethnal Green, Hackney, Bow, and Whitechapel are proud of their park, and justly so, for they have a cricket ground (40 acres), a lake for boating and another for bathing, and they have also a gymnasium, and last, but not least, a magnificent display of flowers that is equal to anything seen in and about London. The designs and planting are varied and excellent—examples of good taste, which afford delight to all beholders. It is gratifying to observe that the people show by their demeanour that they know how to respect these benefits and protect a privilege conceded to them. They look upon the park as their own property, and the authorities do what they can to foster a taste for floriculture. It is evident also that plants are valued by the people of the East, for thousands apply to the Park Superintendent at certain times of the year for cuttings, &c., which the First Commissioner of Her Majesty's Works has

ordered to be distributed among them. As a means of further rendering assistance and instruction plants are grown in the park and exhibited at the local shows. Friendly hints of management are also given, and not without effect, for the working classes exhibit plants that would be a credit to a west-end show.

This park possesses horticultural attractions in no small degree, and maintains the first position for flowers in spring, summer, and autumn. The spring commences with Hyacinths, Tulips, and other spring flowers of various and delicate colours filling the atmosphere with fragrance. Then comes the summer glow with a diversity of colours contrasted and harmonised, producing a picture at once pleasing and satisfying; and after the summer flowers have passed away come the autumn candidates for their share of admiration. The Chrysanthemum receives great attention in this neighbourhood, and an exhibition in the park of this flower attracts thousands

Fig. 72.—VICTORIA PARK.

in the dull days of November. The plants are brought to great perfection through unwearied diligence and care.

Although this is a young park, yet trees abound. There are shady avenues of Limes and Elms, and on all sides handsome specimens are towering above the shrubs, such as the *Pinus excelsa* from Nepal, the *Cedrus Deodara* from India, the Tulip Tree from North America, Cypress trees from California, and on the turf in a recess is a thriving example of *Salisburia adiantifolia*, the Maiden-hair Tree. The deciduous Cypress is growing freely, also the Tree of Heaven (*Ailanthus glandulosa*) and Locust Trees (*Robinias*) flower profusely. The following trees are making good headway:—The Sycamore, the Ash, Horse Chestnut, Birch, the Willow, and the Plane. The park is celebrated for an extensive collection of trees and shrubs of smaller growth. Near the valley-walk leading to the lake is the sweet-scented *Daphne*; the *Cotoneaster*, covered in spring with white blossoms, and in winter with red berries; the red-flowered Currant (*Ribes sanguineum*), one of the hardiest and most handsome of all our deciduous flowering shrubs, is very beautiful with its crimson-red flowers in April and May. Nearer to the lake is a fine group of variegated Hollies and several species of *Spiræas*. On the turf is the Coffee Tree (*Gymnocladus canadensis*) and the Strawberry Tree (*Arbutus unedo*).

A small piece of rockwork has a very picturesque effect; it

is covered with many curious alpine plants, Sedums, Saxifrages, Echeverias, Grasses, and other plants remarkable for the elegance of their foliage. The ground in this part of the park is laid out in the most irregular manner possible, so as to obtain a great number of pleasant walks. The shrubs are mostly planted on raised banks. A number of strong-growing plants are scattered about in front of them, and a few choice specimens on the grass contribute to break and soften the outline of the shrubs.

There are also ornamental sheets of water, islands, rustic bridges, shady and banks. On the islands the Weeping Willow dips its branches in the water, forming an excellent cover for the Muscovy ducks and the timid waterhens. The majestic swan and the keen-eyed China and Barnacle geese may also be seen in company with other aquatic birds. The varied attractions of this park are thoroughly enjoyed by all visitors, and good management is reflected in every department.—NATHAN COLE, *Kensington Gardens*.

#### THE CULTURE OF THE CHRYSANTHEMUM.

As a proof that the Chrysanthemum is not declining in public favour we have only to look around us and notice the many societies which offer encouragement for the cultivation of this grand autumnal flower. In the immediate neighbour-

hood of London the Chrysanthemum is held in great repute; and the provinces are not far behind, for Liverpool, Manchester, Peterborough, Northampton, Oxford, Maidstone, Dartford, Devonport, &c., have their annual shows, and as most of them have fine-foliaged plants and fruits associated with Chrysanthemums, these autumn displays are very attractive. Chrysanthemums are also grown in greater excellence than formerly for home decoration; in fact they are becoming more popular every season, for they not only brighten the duller months of the year, but are adapted to the dry air of heated rooms, in which they remain a long time in a fresh state. The Chrysanthemum is a very accommodating plant, and one which it would be difficult for the novice to kill; but, on the other hand, both skill and patience are necessary to reach perfection, and for this more time, care, and attention are required than can always be bestowed by those who have many garden cares.

In my remarks on culture it must be understood that I have in view perfection of bloom and not symmetry of plants.

When cuttings can be readily procured (which is generally as soon as the plants go out of bloom) insert four or five around the sides of a pot, and place them in a cold frame on a layer of coal ashes to prevent worms from entering the pots. Cuttings put-in in this way strike freely and remain strong and stocky. As soon as well rooted, which is generally about January or February, pot them singly into small pots, returning them again to the cold frame and keeping them close for a few days, affording all the air possible, and if this is carried out with judgment the plants grow slowly but robustly. Immediately they have filled these pots with roots and without becoming matted, which will be about the month of April, the plants will require another shift, this time into 32's, returning them to the frame until all fear of frost is gone; if frames cannot be spared the plants may be protected with mats. At this period of their growth the plants are liable to attacks from green fly, which must be eradicated either by smoking with tobacco paper, dusting the plants with tobacco powder, or dipping them in tobacco water.

From the middle to the end of June the plants will require their final shift into 9-inch pots, which size I consider large enough for plants that are grown for quality of blooms only. But it too often happens that the gardener is more than usually busy about this time, and the Chrysanthemums do not receive the attention which they require, and consequently the final potting is deferred until the roots become matted; this, I would observe, is a prime cause of stunted plants and loss of foliage, and nothing in plant-growing shows defective cultivation so much as plants with long stems devoid of foliage. After receiving their final potting each plant must have a supporting stake, and be placed in a sunny position in the open air; the sides of a gravel path answer well. I formerly thought that with the pots so exposed the roots were liable to be injured, but further experience inclines me to think that though this way entails more labour in supplying water, yet the wood becomes better ripened, and consequently finer flowers are produced; for it were useless to expect perfect flowers from unripened wood.

The plants must be encouraged to grow on uninterruptedly without stopping them, giving them plenty of clear water until the buds begin forming, when manure water may be given freely up to the time the flowers are almost expanded. To ensure large blooms disbudding must be resorted to, and the middle or crown buds of the four or five which appear should be left. The plants require to be supported by strong stakes, these in turn being secured to a string stretched from stake to stake to prevent the equinoctial gales, which often prevail during September, from blowing the plants about and breaking them.

A compost of sound loam three parts, the other part well decayed manure and a good sprinkling of silver sand, well mixed together, is suitable. The pots should be well drained, bones or oyster shells being preferable to common crocks, the bones, &c., affording sustenance as well as drainage. About

a handful of guano to a can of four gallons of water is an excellent stimulant; manure water made from cow and horse droppings, and from guano and soot, also afford a beneficial change of food. By a judicious use of these stimulants after the flower buds are first discernible, the foliage will change as if by magic to a deep rich green. The Chrysanthemum is able to absorb stimulants of a strong nature; but it is not advisable to over-dose the plants, for highly-fed flowers are not lasting, and the premature decay, which is attributed to damp, is more often the result of overfeeding with liquid manure, and which causes also the blooms of some varieties to be both coarse and rough.

Besides as single-stemmed or untrained plants, there are other modes of growing the Chrysanthemum, but wherever the mode described can be carried out in its entirety, and the plants can be

Fig. 73.

staged closely together, they form a magnificent bank of flowers.

The following of thirty varieties are generally prominent in exhibitions of cut blooms:—Mrs. G. Rundle, Mr. G. Glenny, and Mrs. Dixon. All three very good, and most perfect as regards shape, but somewhat small. They are a good trio for the front row for a board of twenty-four. Lady Hardinge, Empress of India, Queen of England, John Salter, Prince Alfred, Isabella Bott, Mrs. Heale, Lord Derby, Jardin des Plantes, Cherub, Prince of Wales, Princess of Wales, Princess of Teck, White Globe, White Beverley, Golden Beverley, Mr. Brunlees, Golden Eagle, Golden Dr. Brock, White Venus, Venus, Eve, Pink Perfection, Antonelli, Lady Slade, Aureum multiflorum, and Gloria Mundi.—J. W. MOOREMAN.

**SPECIMENS.**—To produce plants similar to the one in the engraving, I commence operations about the end of November or beginning of December, by inserting two good cuttings of each variety I wish to grow in a 60-pot. I place these in a frame or a spout hotbed, and keep them close until they are struck. My object in doing this is to have the cuttings struck as quickly as possible, and not to allow them to become stunted, for if once permitted to get into a hidebound state they never make satisfactory plants. As soon as struck I transfer them to a shelf in a warm greenhouse. About the middle of February they are potted singly into large 60's in

a rich compost. The second week in March the plants will be about 6 inches in height and well established. I now take out the extreme point, which induce numerous side shoots to be thrown out—sometimes a dozen, according to the variety. I generally manage to have them potted into 6 inch pots by the middle of April; the side shoots or breaks are then about 5 or 6 inches long, and are pegged down towards the rim of the pot. Shortly after this the plants are removed to a cold frame, and plenty of air is given on all favourable occasions. At this time they grow very rapidly and are again pinched, and potted into 8-inch pots. I may here state, that by taking out the extreme points of the shoots carefully I secure a larger number of strong breaks than by pinching back in a rough manner. If the plants are allowed to have a check at this stage of their growth, either by hard pinching, allowing them to become dry, or placing them in cold draughts, they will eventually present the grower with a number of deformed flowers besides losing a part of their foliage.

I pot my plants for the last time from 8-inch to 11½-inch pots the first week in June, about which time they are pinched for the last time. This stopping will give from forty to sixty breaks, a number which will be found quite sufficient to form a first-class specimen. After being potted into their flowering pots they are taken to their summer quarters; a piece of open ground is provided in the full sun, but sheltered on all sides from wind. I place them on the surface of the ground and surround each pot with ashes up to the rim. I let them grow on after this in their own wild way without any training whatever, giving them every day unlimited supplies of water, adding a little clear soot water two or three times a-week. I find during hot weather that the plants cannot have too much water, provided the drainage is clear. The foliage will also be improved by a watering overhead late every evening.

About the beginning of September the buds will begin to appear. I always select the centre one on each shoot, and remove all others with the point of a small penknife; this operation I perform as soon as I can do so without injuring the centre bud. The ashes are now removed from the sides of the pot to allow the sun and air free access to all parts of the pot and plant, with a view to having the wood thoroughly ripened—a great point to be aimed at, for without ripe wood fine flowers need not be expected.

Earwigs and a small grub are found to be very troublesome at this stage; they must be diligently sought for and destroyed, or the most promising plant will soon be disfigured by their depredations. After the buds are all set I substitute guano water for soot water. I take a good pinch between the thumb and forefinger and rub it well into a small can of water and use at once, a method I find answers very well.

Staking the plants is a very important operation, which requires care, taste and patience. I usually commence tying the first week in October. I will, as briefly as possible, try to describe the way I proceed. The most convenient way is to place the plants on a hand barrow, being careful to have it level. But before tying I give a good dusting of flowers of sulphur underneath the foliage, which can be easily done by turning the plant on its side; this is to prevent mildew. The first stick placed in the centre of the plant must be upright. The sticks I use are about 2 feet long. I now take a shoot and tie it as low down this stick as I can without breaking—a little twisting is sometimes necessary—so that the bud comes directly on the top of the stick. Five sticks are now placed around this central stick in a circle, and they will be found to be about equal distance from the centre stick and from each other. The after-part is a mere repetition, except the outside circle, and these shoots are brought down to the rim of the pot and then tied straight up the stick. I allow my plants to stand outside as long as the weather is at all open, and several of the early varieties only have the protection of an open shed on wet days and cold nights. The plants will grow considerably after this, and the buds will soon be several inches above the sticks; these must be drawn down, carefully working the ties down at the same time until the bud reaches its original position, making a notch above each tie to prevent pushing up again. This mode of culture has led to considerable success both at metropolitan and suburban exhibitions.

It will be seen by the above remarks that I have given dates which are strictly in accordance with my own practice; but if the intending Chrysanthemum-grower can get his plants along earlier in the season let him do so by all means. Early growth, short-jointed wood, combined with thorough ripening, are the chief elements of success.

The compost I use for the final potting consists of good yellow loam broken up roughly three parts, one part well-decayed manure, and a handful of bone dust to each plant, with enough silver sand to keep all open.

Good varieties for specimens are Mrs. G. Rundle, G. Glenney, Mr. Dixon, Mr. Brunlees, Prince of Wales, Lady Hardinge, Guernsey Nugget, Venus, Faust, Dr. Sharp, Alma, and White Christine. The three last-named have reflexed flowers, but the plants are free growers of good habit.—W. HALL.

[The engraving is from a photograph of the smallest plant which Mr. Hall exhibited at the Brixton Show. For exuberance of foliage from the base to the points of each stem, and for the high quality of the blooms, also for the compactness and general finish of the specimen, it is an admirable example of skilful cultivation. The variety represented is Faust, a purplish crimson flower large and incurved.—Eds.]

## NOTES FROM TASMANIA.

THE past winter in Tasmania has been the driest known for many years, no rain falling for six weeks; and after two or three wet days it was again fine for four or five weeks, which is very unusual at this season of the year (September).

During our winter months I often think of the long dull and sunless days of English winters, and think that if the gardeners at home could only secure the bright Tasmanian winters there would be fewer complaints about the difficulties of the early forcing of plants, Grapes, Strawberries, &c., as here it is an exception to have two, or even one sunless day in a week. During June, July and August, which are our duldest months, we frequently have frosts. The severest I have known was 12° Fahr., but by 11 A.M. the sun was as warm and genial as a May day at home. The south wind here is very cold and cutting, similar to your east wind.

We have the following shrubs and plants in open borders planted out without the slightest shelter, and with one exception all remain uninjured during winter and grow most luxuriantly:—*Tecoma jasminoides*, *Polygala myrtifolia*, *P. cordifolia*, *Boronia megastigma*, *B. elatior*, *B. serrulata*, *Clanthus Dampieri*, *Aralia Sieboldi*, *Libonia floribunda*, and *Phormium tenax variegatum*; *Grevillea robusta* being the only plant that appears to suffer during winter. These are only a few of many plants treated as border plants which at home receive greenhouse treatment. Many stove plants are here grown as greenhouse plants.

Tasmania may justly be called a fruit country. I shall never forget the first impressions I received upon landing after a long voyage and seeing the immense quantities of fruit. There is a small Plum grown here very largely, but which does not meet with a very ready sale, as the market is overdone with it. It is a small oval-shaped Cherry Plum, and which in former times realised 20s. to 30s. per bushel. At one place I saw upwards of eighty bushels allowed to fall and go to waste, the price offered not paying for picking. Small fruits are largely grown for the Melbourne market and for jam manufactories. Prices vary from 2½d. to 4½d. per lb. for Black and Red Currants and Raspberries. Apples and Pears realise in Tasmania from 2s. to 4s. per bushel wholesale, but a much higher rate in Melbourne. The soil and climate here are admirably adapted for fruit-growing. Apricots, Peaches, Grapes, &c., grow and fruit abundantly. Apricots and Peaches grow as standards and produce fine-looking fruit, although I do not think the flavour so good as at home.

The bush at this season of the year begins to look very gay. The Acacias are now in full bloom. In some parts the sight is grand, as for miles all along the roadside are Acacias from 3 to 40 feet high, completely covered with rich golden flowers; while the small Epacris, Heaths, and Orchids are beginning to unfold their colours.

I think Tasmania is well entitled to share honour with New Zealand as being the paradise of Ferns. In my rambles through the bush I have seen some magnificent valleys of Ferns in their rich wild beauty. Upon the N.W. coast I saw a fine patch of *Gleichenia speluncæ*, which had fastened itself to the undergrowth. I measured the patch, it was 30 yards round and 7 feet high. There was not a place around it where I could get my hand through without displacing the foliage. It was growing in a swampy creek. I was struck with its great beauty, and was sorry to think how fast these fine examples of Ferns are disappearing owing to the bush fires. After a fire has passed over them they still live, but never recover their beauty. I recollected the specimen *Gleichenias* which

were disposed of at the Manley Hall sale in 1872, and compared the difference—the care and attention they received, and here in the wild bush, without any care, and scarcely an admirer to preserve these and many other Ferns for future generations. They are, like the Aborigines, fast disappearing from all the settled districts. For instance, I have heard of persons cutting down the Dicksonias and bracing them together to form a hut to live in; others cut them down and split them open to feed the pigs upon the pithy substance in the centre. In some places the Ferns are not found growing, while in distant gullies they are very plentiful, but as soon as the scrub and timber is taken away and they are exposed to the dry atmosphere they turn sickly, and never flourish afterwards.

It is a great pity that in Tasmania, with all its natural advantages, gardening is not carried on with greater spirit than at present. Gentlemen do not enter into it with the enthusiasm that is needful for success. There is a horticultural society in Launceston, which holds three and sometimes four shows in the year, while one or two other towns in the north have a society—i.e., Longford, Evandale, and Deloraine. The plants, &c., are not allowed to be removed from the show till the following day, as it is generally found to be very profitable to the society to have it open during the evening.

In conclusion I would say to any young men intending to emigrate to the Australian colonies, Throw away before starting all high and lofty ideas about gardening, and become willing to adapt yourselves to circumstances, as the duties of a gardener are very different here to what they are at home, and until a man gets used to the change he feels very discontented, and regrets leaving England. Still, to young men of steady industrious habits there are openings of promise in the continental part of Australia.—F. W., *Launceston, Tasmania*.

### EUCALYPTUS GLOBULUS.

In March, 1875, I bought a small tree in a pot, which I kept in my unheated orchard house, and planted this tree in the centre of my walled garden in September. It was then about 4 feet high, and as thick as a fair-sized finger. I put some spent seaweed round the stem, but the frost at the end of November killed it. At the same time (March, 1875) I sowed a packet of seed in a pan, and raised some twenty-five plants. I transplanted these into three or four large pots, seven or eight in a pot, and early in October I planted ten strong plants out near a 6-foot wall facing the east. These were from 18 inches to 2 feet high. I put some manure round the stems for protection. They all did well, and are now from 4 to 9 feet high. I moved two of these about 4 feet high in September last, and I think they will die. I do not think they move well, for their roots are small and do not extend, and they have an abundance of foliage. I sent plants to a gentleman at Penzance, and when I heard last they were thriving.—Wm. K., *Arundel*.

I FOUND an Eucalyptus about 18 inches high planted-out on the lawn when I came here (May, 1874). It grew very rapidly. The leaves browned and withered in the winter, but it revived in spring. In the September gales of 1875 it lost its leader when it had attained fully 14 or 15 feet. Last winter it suffered as before, looking if possible more hopeless than ever, but spring restored its beauty, and it is now a handsome bush, untouched as yet by the frost. It has never had any protection.—BOURNEMOUTH.

I HAVE grown this for three years, raised originally in a hotbed, and kept one winter in a greenhouse, then growing too large it was planted amongst shrubs—grew 7-6 high. In the winter of last year, although bound round with straw, it was cut off and killed by frost. The same year in the same garden smaller trees stood the winter, and are now doing well, but have not run up. I intend to let them alone, and my impression is if we have hard frost they will die. I do not think they will stand English winters, and I am told that at Nice they suffer much (although large trees) from frost. I will report results in the spring.—F. C. HASSARD, *Sheerness*.

### PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

MIRABILIS MULTIFLORA. *Nat. ord.*, Nyctaginaceæ. *Linn.*, Pentandria Monogynia. Flowers crimson.—“This strikingly beautiful plant was raised from Californian seeds by Mr. Thompson of Ipswich, who sent flowering specimens to Kew

in July of the present year. It has apparently an extensive range, from the forks of the Platte river, in lat. 42° N., where it was discovered by Dr. James in 1820, to Mexico, where it was found near Zacatecas, in lat. 23°, by Coulter, and subsequently in New Mexico by Wright and Fendler.”—(*Bot. Mag.*, t. 6266.)

TURRÆA OBTUSIFOLIA. *Nat. ord.*, Meliaceæ. *Linn.*, Monadelphia Decandria.—“A shrub, native of woods and bushy places in the eastern districts of South Africa, extending from Albany to Natal, apparently most common in the eastward; it also occurs as far north as Lake Ngamo in latitude 21° south, where it was gathered by McCabe, and in Sechualis country, the specimens from whence have narrower leaves. The genus *Turræa* consists of pretty white-flowered shrubs and small trees of tropical Asia and Africa; about sixteen species are known. *T. obtusifolia* was raised from seeds sent to the Royal Garden by H. Hutton, Esq., of Graafreinet, in 1872, which flowered in the present year.”—(*Ibid.*, t. 6267.)

MASDEVALLIA TRIARISTELLA. *Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Densely tufted dwarf flowers, yellow and crimson.—“*Masdevallia triaristella* was discovered in Costa Rica by Endres, and flowered by Messrs. Veitch in September last.”—(*Ibid.*, t. 6268.)

MUSCARI ÆSTIVALE. *Nat. ord.*, Liliaceæ. *Linn.*, Hexandria Monogynia. Flowers yellow, top ones pink.—“This is a near neighbour of that old and well-known garden favourite, the Musk Hyacinth, *Muscari moschatum*. Besides its botanical characters, our present plant differs from *moschatum* by its faint scent and much later time of flowering. It came from the rich bulb collection of H. J. Elwes, Esq., of Miserdine House, Cirencester, and flowered in his garden at the middle of June, 1875. He procured it from Messrs. Haage & Schmidt of Erfurt, and does not know its exact country, but no doubt, like its allies, it comes from some part of the rich Oriental region.”—(*Ibid.*, t. 6269.)

MONARDELLA MACRANTHA. *Nat. ord.*, Lamiaceæ. *Linn.*, Didymia Gymnospermia. Flowers crimson.—“A very beautiful, highly aromatic Californian plant, described by Asa Gray very recently, and apparently local, as he gives but three localities for it—namely, the Cuimáca Mountains, near Julian city, and north-east of San Diego. Our cultivated specimens differ from Gray's description in the close heads of flowers, in the corolla not reaching 1½ inch in length, and in its brighter colour, being more scarlet than orange-red. It was raised by Messrs. Veitch from Californian seeds, and flowered in October of the present year.”—(*Ibid.*, t. 6270.)

KERAMANTHUS KIRKII. *Nat. ord.*, Passifloræ. *Linn.*, Diœcia Pentandria.—“*Keramanthus Kirkii* is stated by Dr. Kirk to be very common at Zanzibar, where it is planted, like the *Jatropha Curcas*, to mark the site of graves. It flowers at Kew during the greater part of the year; our tallest plant is 2 feet high.”—(*Ibid.*, t. 6271.)

PLUM—Frogmore Damson.—“Our old varieties of Damsons are very few, the principal kinds grown being the Common, the Shropshire, and the Yellow. We may, therefore, with pleasure welcome a new and improved variety of this class of fruit, and such is the subject of our plate, which represents a Damson that is not only new, but distinct from those enumerated above. It originated, as its name implies, in the Royal Gardens at Frogmore, and although a few years have elapsed since it was raised and distributed, it is not so well known as it deserves to be. The habit of the tree is different from that of the usual type, since it has broader leaves, is of spreading growth, and has the shoots less thorny. It is an enormous bearer. The fruit is a trifle larger than that of its class, of a purplish-black colour, and inclining to obtuse-oval in shape. The flesh is tender and richly flavoured. It is suitable for all the purposes to which Damsons are applied.—J. POWELL, *Frogmore*.”—(*Flor. and Pom.*, 3 s., ix., 265.)

### NOTES AND GLEANINGS.

At a meeting of florists, held at South Kensington yesterday, Mr. Thomas Moore in the chair, it was reported that Francis Whitburn, Esq., had accepted the office of President of the southern branch of the National Auricula Society, and had offered a donation of £5 to the prize fund; and that the Crystal Palace Company had promised a donation of £10, and named April 24th as a suitable day for the Show. Dr. Hogg, Dr. Masters, Dr. Denny, G. F. Wilson, Esq., Mr. Cutbush, and Mr. Lidgard were added to the general Committee; and Mr. Turner, Mr. Dodwell, and Mr. Douglas were nominated a sub-

committee, to arrange a schedule of prizes for Auriculas and Polyanthus. Subscriptions amounting to upwards of £40 have been promised, and further offers of support may be sent to Mr. E. S. Dodwell, Larkhall Rise, Clapham.

— We lately noticed flowering in the collection of Messrs. Veitch & Sons at Chelsea a plant of *LIPARIS PENDULA*, an interesting Indian Orchid. It is not of recent introduction, nor are the individual flowers of great beauty, yet are noticeable as resembling those of Mignonette, and are scented like that choice old favourite. They are borne on recurved spikes 9 inches in length.

— We have two letters, one informing us that *GARIBALDI STRAWBERRY* was raised by Mr. Armstrong of Botherby, Carlisle, and the other by the late Mr. Nicholson of Eaglescliffe, Yorkshire; while a third writer asserts that Garibaldi and *Vicomtesse Héricart de Thury* are synonymous. The fog thickens. Mr. Wm. Thomson says that "Garibaldi has the property of enduring more frost when blossoming than any other variety."

— A CORRESPONDENT "J. L." informs us that he has grown *MASTERS' PROLIFIC CUCUMBER* for several years, and has found no other to equal it for bearing either in summer or winter. "It is," he says, "well named Prolific, for you may cut a brace or two almost every time you want them. It grows from 10 to 12 inches in length; it has a short neck, and is very tender and good-flavoured."

— AMONGST the foreign productions in COVENT GARDEN MARKET we recently observed some fine heads of *Globe Artichokes*, which we were informed had been sent from *Marseilles*. They appeared to be of excellent quality, and were as fresh-looking as if only brought from Fulham.

— FEW plants are more easy of cultivation in pots than the *CHRISTMAS ROSE*, *Helleborus niger*. Of late years this valuable old plant has become extremely popular, as affording large white flowers in the depth of winter, when such flowers are always valued. The Christmas Rose grows and flowers freely in 5 and 6-inch pots, which need only to be plunged over their rims in the garden in summer and be removed to a cold frame in the autumn, to aid their flowers in expanding and keeping them clean. The plants do not need to be potted oftener than once in two years, as they are somewhat impatient of having their roots disturbed. Plants thus established in pots are very valuable for the decoration of the greenhouse and conservatory.

— THE weather for several days past has been extremely wet in London and its vicinity, and garden ground, except where very light, has been totally unworkable. The daily rains have been accompanied by mild temperature; and many green crops, such as Spinach, Cabbages, Lettuces, &c., are growing freely—possibly too freely, for should a term of frost suddenly occur these crops would not be likely to resist its severity. The winter's supply of green vegetables which at one time were so prospectively scarce, is so far equal to the demand, and both green crops and root crops are plentiful and good. Slugs and snails are also plentiful, and are making the most of the mild weather. The season has been favourable for the planting of trees and shrubs, and trade in these has latterly been brisk in many nurseries.

— MR. MERRYWEATHER, Southwell, Notts, has sent us fruit of a kitchen Apple named *BRAMLEY'S SEEDLING*, a variety which we are informed is rapidly rising in public favour in the midland counties. The fruit is large, in appearance somewhat resembling *Ecklinville Seedling*, and is very heavy. The flesh is white, juicy, and melting, and has a brisk sparkling flavour. If this Apple sustains its character as being as "hardy and free in growth as *Blenheim Pippin*, and as productive as *Dumelow's Seedling*," it cannot fail to become valuable for orchard-planting. We will submit the fruits to a more careful examination, for it appears to be a meritorious variety. We should like to know its history.

— We have received from Mr. Bell of Clive House, near Alnwick, a new black SEEDLING GRAPE of great promise. It resembles the *Black Alicante* more nearly than any other variety, but is decidedly superior to that fine-looking Grape. The berries of the seedling are of the same shape as those of *Alicante*, are perfectly black with a leathery skin and stout warted footstalks. It is evidently a free setter, every berry being equal in size, closely packed, and well formed. The flesh is firmer than that of the *Alicante*, and the flavour and quality are certainly superior, although the bunch was not in perfect condition. We think highly of this Grape, and con-

gratulate Mr. Bell on raising such a distinct and promising variety. Mr. Bell's vineries were described in our columns on page 420.

— THE best kinds of *VARIEGATED HOLLIES* are deserving of more attention than they generally receive as winter decorative plants. For balconies, terraces, window sills, halls, and staircases, also for lawns, shrubberies, and flower beds, these bright and cheerful shrubs impart colour and beauty which cannot be equalled by any other hardy plant. No *Coleuses* in summer are so distinctly bright as these *Hollies* in winter, yet there are very many gardens which do not contain them. They are villa-garden shrubs *par excellence*, and should never be forgotten at this the period of planting time. Moderate-size shrubs remove safely from now until April when the weather is favourable.

— AT the SMITHFIELD CLUB CATTLE SHOW Messrs. Sutton and Son, the Queen's Seedsmen, Reading, have an imposing stand. The whole of the specimens are of that clean growth which denotes great care in the selection of the stocks, the importance of which cannot be over-estimated. The back of the stand is occupied with a collection of Grasses, consisting of upwards of three hundred different varieties, and including all those which Messrs. Sutton use in the preparation of their Grass-seed mixtures. It is most essential in laying down land to Grass to sow such kinds as are suitable to the peculiar geological formation, and this has been a special study of the firm for well nigh half a century. Among the Potatoes are Sutton's Redskin Flourball and Sutton's Hundredfold Flake, as well as their new late white kidney "Magnum Bonum." This, they say, promises to be one of the best white kidney varieties in cultivation, being very robust in habit, possesses a strong constitution, and is remarkably free from disease, while it is mealy and an extraordinarily heavy cropper. Messrs. James Carter & Co. have a similarly large and good display at the same Show, which we will notice further next week.

## NOTES ON VILLA AND SUBURBAN GARDENING.

THE conservatory or small greenhouse will be the principal attraction to amateur gardeners now and for some time to come, and to render the enjoyment of these structures complete the plants must be kept perfectly clean and healthy. This cannot be done without constant attention. Means should also be taken that the interior of the house be kept clean in every part. Every plant should be looked at, and all decayed leaves should be removed; all damp should be dried up by gentle fires in dull or wet weather, and watering should be done in a more careful manner than at any other time of the year. Persons who are not practically familiar with plant culture may easily make very serious mistakes in watering. However, it must not be considered that a plant will require as much water in winter as in summer unless it is subjected to a very high temperature, and here is when judgment is needed; and as some plants require more water than others, those which are over-watered are soon destroyed.

The object of watering should be to prevent an amount of dryness being reached which is injurious to the plants, and, on the other hand, not to apply water in excess of what the plants really require, for in that case the soil becomes gorged and soddened, and the plant languishes. If cultivators like to work within these limits there need be no fear of their plants suddenly going wrong.

Scarcely any of the ordinary greenhouse plants will bear growing-on quickly in these dull months, for if so the growth is weakly, and when the time for flowering comes the flowers are not only small but the colour is imperfect. Avoid overcrowding as much as possible, because air ought to circulate freely among the plants if they are to be kept healthy; and plenty of light too is an indispensable element—quite as much so as air, and in order to have light the plants should be kept as near the glass as possible. Let watering be done before mid-day, so that the plants as well as the house be quite dry before night. A continual dampness of the house must be particularly avoided, for it brings on mildew and many other diseases.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

THERE has not been much done in this department different from what was detailed in a previous number, and the instructions there given (page 451), if they have not been followed out, ought no longer to be delayed. The present is the best time for planting all kinds of fruit trees; and if the ground is not yet prepared it may still be done. But although the present is the best time for planting it is not the only time, as the trees may

be successfully planted until March; but those who cannot plant their trees until that time ought to purchase them at once. The nurserymen will either send the trees home, when they can be laid-in until wanted, or they may be marked and sent at any other convenient time. The principal preparation of the ground required is trenching and draining. In soils not naturally drained the latter operation is the most essential. Apple trees in undrained soil soon become covered with mosses and the fruit with fungus, and the fruit is very inferior to what it would have been on well-drained soil.

The distances for planting must also be considered. Mr. Rivers has recommended 3 feet apart for trees on the dwarfing stock. At Clements near Ilford a large plantation was made and the trees were planted 6 feet apart, but it was soon found that this was too close. Every alternate row was then taken out, which left the trees 12 feet one way and 6 the other. This was also found to be too close, and every alternate tree was taken out of the rows, which left the trees as they are now 12 feet apart, and this is a very good distance for bush trees on the Paradise stock. Orchards are not usually planted with these trained bush trees, but they are preferred by many growers to the usual system of standard trees with straight stems from 4 to 6 feet high and the trees 20 feet apart. In some soils the dwarf-trained trees might be even 6 feet apart. In heavy clay the trees have a great tendency to produce fruit when only three or four years old, and in lighter soil to run more to young wood. In the soil at Sawbridgeworth the two and three-year-old trees may be seen bristling with blossom buds with very little young wood, and from observations obtained amongst such trees Messrs. Rivers in their catalogue recommend the trees to be permanently planted much closer than is desirable on light soils.

Those who plant their trees from 18 to 20 feet apart, if the ground is not laid down with grass, will crop between the trees, but this system of cropping the ground must not be carried too far. Sometimes Strawberries are planted between the trees and give a profitable return, but any kitchen-garden crops may be cultivated, those of a dwarf habit to be preferred. The first year the ground may be cropped to within 2 feet of the trees, next season 3 feet, and the third year the ground ought not to be cropped nearer than 4 feet, but much will depend upon the size of the trees and their growth after planting. In digging the ground great care is necessary to avoid injuring the roots. It is better to dig over them, but it must be done carefully with a digging fork; indeed, this implement is much more efficient for all purposes than the heavier and more clumsy spade. Apple trees are by far the most useful to plant in an orchard, and bear the most regular crops. Some of the more hardy sorts of Pear, Plum, and Cherry trees may be planted, but birds have a great fancy for Cherries, and they will have them whatever precautions are taken. Pears and Plums are an uncertain crop.

#### PINE HOUSES.

We find that to have Queens ripe in May it is necessary to start them into growth by the middle of this month. Our plants have been kept dry at the roots and the atmosphere quite cool, and very little artificial heat has been necessary for keeping up the temperature to 55° or 60° at night. When the house is started the temperature is raised about 5°. The plants are thoroughly watered at the roots, and it is well to turn the tan beds over and to mix some fresh tan with the old material; this will sometimes raise the temperature of the bed too much—indeed, we have occasionally had the bottom heat raised to 110° from merely turning the bed and adding a little fresh tan to it. This is far too much: 90° or even 95° as the maximum is sufficient, and if the thermometer stands above those figures the pots must not be plunged to more than half their depth in the beds. A high temperature in the beds does more harm than many people are aware of. If the pots are well filled with healthy roots the plants generally throw up fruit freely, but it is as well not to give too much water until signs of fruit can be seen deep in the centre of the plants; even then too much water may be applied. If the pots are plunged to the rims in moist tan it is not likely that the roots will want water more than once a week, or perhaps not so often as that.

One of our fruiting houses has been cleared of plants, and in another house are Pines in various stages of development. They will be placed in a house where they can be kept warmer, 65° at night with the temperature rising to 75° or even 80° when the sun shines brightly. The change to a warmer house will be beneficial to the plants, and some of them will throw up at once, others will start growing a little before doing so, but the latter plants will no doubt produce the best fruit, and if it is later so much the better, as we do not require many Pines to be ripe at one time. The temperature of the succession house is best kept about 55° for a month longer; as the days lengthen after Christmas this may be gradually increased.

#### PEACH HOUSE.

The instructions as to preparing the trees when in a dormant state is so similar to that given under the heading for Vines, that it is not necessary to say much about it here. The earliest

house ought to be prepared at once if it is not done, and if any brown scale has formed a lodgment on the trees it ought to be removed by washing it off with rain water in which has been dissolved some soft soap. Any Peach aphides which may be clustering on the young wood ought to be removed in the same way preparatory to painting the trees with a mixture of soft soap, sulphur, and a little tobacco liquor. This ought not to be made quite so strong as has been recommended for Vines, else it is likely to cause the buds to drop.

A not uncommon mistake with the inside borders of Peach houses is to allow them to become too dry, and when water is applied abundantly to the roots it is not unlikely that many of the blossom buds will drop off. In places where gardeners are required to keep up a succession of Peaches from May till November it is quite time that the first house was started by giving the border a good supply of tepid water, and closing the house early in the afternoon to take advantage of sun heat. The night temperature for the first ten days ought not to fall below 45°; for the next fortnight 50°, rising by the first day of the new year to 55°. The trees ought to be dewed over on the mornings of dull days with tepid water, and when the sun shines in the afternoon shut up about 2.30, and again syringe them. A pot of rain water ought always to be standing on the hot-water pipes for this purpose.

#### GREENHOUSE AND CONSERVATORY.

In previous numbers mention has been made of the care required with hardwooded plants during the winter months. At present the minimum supply of water should be given to them, and the quantity required will depend much upon the state of the roots of the plants and the time since they were last potted. We have some specimens potted last September, and the roots, of course, have not nearly filled the fresh compost. These require but little water; but what they do require must not be given in dribbles, but the plants ought to be allowed to become sufficiently dry, and then enough water must be given to moisten the whole ball of earth. This is the right system of watering with all plants, but it ought more especially to be insisted upon when delicate plants are in question at the duldest period of the year. Any water that falls upon the paths ought at once to be wiped up, and all the watering ought to be done early in the day.

We have tried propagating our own plants and also purchasing from the nurserymen to keep up a supply, and unless in the case of new, very rare, or choice plants, it is not worth while to propagate them ourselves; they can be bought much cheaper, and the labour that is spent on their propagation and after-management be advantageously diverted into other channels. We generally buy a few about July or August, and the plants, as a rule, require at once to be shifted into larger pots. August or early in September is as good a time as any to repot them. They will usually require another shift in the following spring—say February or early in March.

The present damp muggy weather has been trying to plants in flower. The *Crowea saligna* major stands damp better than any other flower we have at present. *Lapageria rosea* and *L. alba* have both suffered, and the perpetual-flowering Carnations have not opened well owing to the want of sun, and the petals occasionally become mouldy; these fine flowers open well in a night temperature of 50° and a rather dry atmosphere. Damp is very injurious to them; all mouldy petals ought to be promptly removed to prevent further decay.

A few plants of *Cyclamens* may be moved into a house where there is a night temperature of 50°, with considerable ventilation during the daytime. They will come in earlier than those in the ordinary greenhouse temperature, and prolong the season of these useful spring flowers. Large plants of *Cyclamens* are apt to suffer from damp and mould settling on the flowers in the centre before they rise above the foliage. They ought to be watched for this, and when water is applied it ought to be done by carefully pouring it in round the sides of the pots. The plants must not be placed too closely together, and they ought to be as near to the glass as possible.

Stage and fancy *Pelargoniums* should be placed in a light airy position, the plants to be kept free from any decaying leaves, and the house to be frequently fumigated to destroy green fly. *Cinerarias* also are kept near to the glass, and as the plants increase in growth the shoots are tied out. Aphides are particularly fond of feeding on the under sides of the succulent leaves, and whether any are observed on the plants or not it is best to fumigate frequently during the winter months.—J. DOUGLAS.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

NEWCASTLE-UPON-TYNE. March 21st and 22nd, 1877. Messrs. J. H. French, Benwell House, and J. Taylor, Rye Hill, Hon. Secs.  
WISBECH. June 23th. Mr. Charles Parker, Hon. Sec.  
ISLE OF THANET. August 30th. Mr. C. D. Smith, Hon. Sec.

## TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*J. M. and others*).—The book you require is published at this office, but is now being reprinted.

GRAFTING VINES (*A Working Gardener*).—The Grape sent is the Black Morocco, which is a good late Grape, requiring stove heat to ripen it perfectly, and special care in setting its berries, a globe of liquid frequently forming on the stigma and impeding fertilisation. This moisture should be removed by gentle agitation, so that the pollen may come in contact with the stigma. You may graft or inarch any of the Vines you name. You will find useful information in our Nos. 617 and 806, which can be had post free for 7d.

WEST INDIAN PLANTS (*A. Henry*).—There are hundreds that grow wild in the West Indies that are now cultivated in our glazed structures; but it is impossible to select from those plants. Tell your friend to bring cuttings, or seeds, or bulbs of those which are beautiful.

FINES DECAYING AT THE CORE (*E. B.*).—The cause of this is either giving the plants too much water after the fruit has become nearly ripe, or applying manure water at that stage.

VENN'S BLACK MUSCAT GRAPE (*Reader*).—This variety has not yet been sufficiently tested as a late Grape, but we do not think it will keep so well as Lady Downe's or Alicante, but we certainly advise you to try it in your late house with those two sorts.

PEAR TREES UNHEALTHY (*C., Halifax*).—Judging from the spur sent we suspect the cause of the unhealthiness of your trees to be ungenial and possibly water-logged soil. If the soil is wet drain it thoroughly to a depth of 3 feet, having a clear outlet for the water. If the subsoil is not wet, then the condition of your trees is attributable to poverty of the soil. The remedy in this case is to remove the surface soil, just baring the roots, and cover them with the best soil you can obtain, and over the soil place a good covering of rich manure. Limewash the trees, or, what is equivalent, dust them with dry lime when the branches are wet. If blossom buds predominate over wood buds remove some of the former, especially taking off any at the tips of the branches. Your aim must be to induce clean healthy young shoots, not permitting the trees to blossom profusely, and your trees will regain their vigour.

RANUNCULUS.—In my paper on the Ranunculus there is an error. I am made to say 'as to soils,' when it should have been 'as to sorts.'—*D., Deal*.

SMALL ORCHARD (*Constant Reader*).—Go by rail into Devonshire or Somersetshire and search.

SUTTONS' RED-SKIN FLOURBALL POTATO (—).—The produce from 1 lb. of seed as exhibited at Reading by Major Thoyte was 267 lbs.

LINE (*A Constant Reader*).—To improve the staple the quantity you name is far too small. If to furnish calcareous matter to the crops it is enough.

WOOLLY REFUSE (*T. M.*).—It would be long in decomposing, but, like all animal refuse, would be fertilising when decayed. It would be most useful if applied to a heavy soil.

LAWTON BLACKBERRY.—*J. M.* and others wish to know where they can purchase plants of this Blackberry.

BARKEET PLANTS UNHEALTHY (*Nolens Volens*).—The cause of the plants not succeeding is due to their unsuitability for so dry an atmosphere. Musk and Lobelia like moisture, and they with Geraniums are at too great a distance from the window. More suitable plants for the position would be *Campanula garganica*, *Saxifraga sarmentosa*, *Mesembryanthemum cordifolium variegatum*, *Sedum Sieboldi*, *S. azoideum variegatum*, *Antirrhinum procumbens*, and *Cereus flagelliformis*.

HEATING PLANT-PRESERVER (*A. M.*).—You will need a 2-inch pipe all round the frame so as to exclude frost, and if you contemplate forcing, 2-inch hot-water pipes all round the inside of the pit will be necessary. We do not think you can satisfactorily heat the pit from your present boiler, as all the pipes you would have would be returns, and all below the boiler, besides which water would be repeatedly drawn from the hot-water cistern, or boiler, or both, and you would need to disconnect the present return pipe to the boiler from the hot-water cistern, so as to cause the water to return by the frame pipes. The action of such an apparatus would be very sluggish and uncertain in its action, and we think would prove unsatisfactory. We advise a separate boiler, but there is no question but that the frame would be more economically heated from the house boiler were it not that the boiler is above the level of the floor of the frame.

NAMES OF FRUITS (*Connaught Subscriber*).—Knight's Monarch. (*J. Bryan*).—1, Tower of Glamis; 2, Golden Noble; 3, Toker's Incomparable. The Pear was quite rotten.

NAMES OF PLANTS (*J. E.*).—1, *Chrysanthemum pallens*; 2, *Pyrethrum frutescens*. (*J. P.*).—1, *Schizostylis coccinea*; 2, *Veronica salicifolia*; 3, *V. angustifolia*. (*A. Novice*).—1, *Aster* sp.; 2, *A. Novi-Belgii*; 3, *Lonicera japonica aureo-reticulata*. (*S. J.*).—1, *Calanthe* sp.; 2, *Maxillaria picta*. The shrub is *Benthamia fragifera*. (*T. R. L.*).—2, *Asplenium bulbiferum*. 6, *Lastrea dilatata*; 7, *L. spinulosa*; 8, *L. Filix-mas*; 10, *Polystichum argulare*, var. The remainder immature. (*H. S. K.*).—1, *Cytisus canariensis*. Material insufficient of remainder. (*Ban Ousel*).—1, *Pteris serrulata*; 2, *Adiantum formosum*; 3 and 5, material not sufficient; 4, *Selaginella cuspidata*. (*Woodcote*).—2, 3, 5, 6, 7, monsters of *Filix-femina*; 1, of *Filix-mas*; 4, of *Polypodium vulgare*. (*J. H.*).—1, *Nephrolepis cordifolia*; 2, *Aspidium falcatum*; 3, *Adiantum hispidulum*; 4, *Pteris cretica*; 5, *Pteris flabellata*; 6, *Pellaea rotundifolia*. (*Lady Subscriber*).—1, Material insufficient; 2, *Adiantum formosum*; 3, *Nephrodium setigerum*. (*Mrs. Newman*).—1, *Pteris cretica*

var. *albo-lineata*; 2, *Pellaea rotundifolia*; 3, *Pteris serrulata*. Dip the plants in soft-soap water occasionally to prevent thrips. (*A Constant Reader*).—*Cerinthe aspera*, Rough Honeywort. (*Mr. Downes*).—*Urceolina pendula*. (*T. R.*).—We do not remember your Ferns; if received they were sent to the botanist who attends to the subject, and will be answered by him.

## POULTRY, BEE, AND PIGEON CHRONICLE.

## BIRMINGHAM CATTLE AND POULTRY SHOW.

DECEMBER 13TH, 14TH, 15TH, 16TH, and 18TH.

THE unprecedentedly large entry received in every department proves the soundness of the change of date adopted by the Council this year; nor will the increase in numbers, we are assured, be obtained by the sacrifice of anything in the quality of the exhibits. On the contrary, visitors to Bingley Hall will there see together the conquerors in their various classes at the London, Edinburgh, Leeds and Oakham Shows, which are all held the week previous to Birmingham, and will therefore act as feeders to the great midland Show.

The show of potatoes will extend to nearly four hundred dishes, the prizes being most liberal in this section.

The Poultry and Pigeons, which number over 2700 pens, would, if placed in a single line, reach something like a mile and a half, and will be a grand exhibition, the time of year being most favourable to the display of plumage.

The charges for admission have been somewhat modified; but on Wednesday, the day of judging, will remain at 10s., except for life members, who receive a free pass for the whole Show. On Thursday, the fashionable day, on which day the Dog Show also opens, the admission is 5s. until five o'clock, and 1s. after. On Friday, 1s. all day; and the same until two o'clock on Saturday, when it is reduced to 6d., which price is also the figure for the whole of Monday, the last day.

The arrangements of the various railway companies will be on a most liberal and extensive scale. Excursions will pour in daily from all populous parts. Hereford, Shrewsbury, the Potteries, Yorkshire, Derby, and the colliery districts, Northampton, Bedford, Oxford, Worcester, and all intermediate places will have special facilities at greatly reduced rates, either by one or three-day trips; whilst, to come nearer home, trains will run from Walsall, Wolverhampton, Stourbridge, and Kidderminster every half hour, or as often as required.

## BRISTOL POULTRY SHOW.

DORKINGS as usual headed the list, and therefore first demand our attention. Taken all round they were not equal to the Show in some former years at Bristol, probably a number of good birds are being kept back for Birmingham. In Coloured cockerels first came the Palace cup bird, in blooming condition; he has grown much since the Palace, and we thought he deserved the cup for best Dorking cock; still this mattered little, as his owner's Silver-Grey cock had it. Second was a bird of much the same type, a medium colour but not so large. The third we did not admire; there is something odd about the back of his comb, and he has much white in breast and hen feather of tail; his feet are white and good. Fourth we thought decidedly better, he is very dark and promises to grow much. We admired Mr. Hamilton's very highly commended bird, but thought his legs rather too red. The pullets were not a good class—first was excellent in colour, not a striking bird or very white in feet; she is long and will probably make a good hen. Second a well-shaped square pullet. Third rich in colour and large, but a little ungainly. Fourth as good as any in the class, broad and square. The second and very highly commended (Cresswell and Watson) were both good, of the old-fashioned colour, slightly laced. We are glad to see this colour again coming into favour. Cocks were but a small and poor class. First was a massive Dorking in good condition. Second a nice dark bird, but purple in comb and not well. Third White, but rather gouty in feet with a drooping comb. Hens were a much better class, and as at the Palace the birds were in wonderful condition. First a capital bird, we think not her owner's cup bird at the Palace; she is very large with good white feet. Second also good in feet, a long bird too stilty. Third a good hen in colour, and square in shape. These three prize birds were as good hens as one could wish to see. 43 (Bartrum) is a beautiful dark bird, but she seemed rather shaky on legs. Silver-Grey cocks were few. First a very fine and silvery bird, he was awarded cup for the best Dorking cock; he is the bird which we mentioned as hardly receiving his due when third at the Palace. Second well through the moult, but yellow in hackle and white in breast. Third a moderate cockerel. In hens a grand old bird was first; she is nearly eight years old, and figured in the prize lists as long ago as the year 1869. Second a large hen, browner than the first. Third not good in size or colour. Whites.—First, the first Palace cockerel, he is a grand Dorking in shape, but now becoming rather coarser in comb. Second a very fair cockerel, which we

think we mentioned at the Palace. Third Mr. Boissier's glistening White bird. Dr. Snell showed a cockerel in this class suffering severely from the "new disease;" the bird was very properly sent home with some of his companions on the second day of the Show. We only trust that the complaint may not be disseminated from him, and earnestly hope that exhibitors will not risk causing irreparable loss to their neighbours by sending birds about in such a state. The first White hen was magnificent, the cup bird twice at the Palace and at many other places. Second a poor little bird without proper development of the fifth toe. Third a fine hen, but with one foot somewhat crippled. We should certainly have put Mr. Boissier's highly commended bird second. 73 (Haynes) a fine pullet but yellow.

**BRAHMAS.**—*Dark.*—Mr. Lingwood's Palace cup bird was again to the fore; his head is one of the smallest and most beautiful we ever saw. Second a very nice bird with good orange legs; his comb is a little too high behind, his breast minutely and prettily ticked with white. Third too large in tail, otherwise a very good bird. Fourth hardly equal to the first three, still a nice bird; he does not rise quite enough towards the tail. Mr. Hamilton seems likely to become as great in Brahmas as in Dorkings. We thought 296 (Pritchard) the next best to the prize birds. The class was not good throughout. First-and-cup in pullets was the Palace cup bird, which we have before described. Second a Silver-Grey bird with small and delicate breast-pencilling, much to our fancy, though a little white towards the throat; her shape is nice. Third well marked all over, specially on the back. Fourth poor in leg-feathering; hardly Mr. Lingwood's type of bird; her pencilling clear all over, though rather blunt. The old birds were better than the young, and in better condition. The first cock was in strikingly blooming trim for an adult; the gloss on his wings and tail was wonderful; he is black-breasted, hooked, and moderately marked in hackle. Second not in good condition, fine in shape and foot-feathering, with densely striped hackle and much white in tail. Third a true Lingwood type of cock; we think his condition should have placed him second. Hens were a capital class. First was as perfect a bird in the whole of her markings, especially on the back and cushion, as possible; she is a little deficient in size and leg-feathering. Second a large and well-pencilled bird, hooked, and a little browner than the first. Third not quite so massive or heavily feathered as the second. 340 (Lingwood) a very fine heavily feathered hen. There was hardly a bad bird in the class. *Light* were by no means equal or nearly equal to the Crystal Palace classes, though many capital birds were shown. The first cockerel was very good in style, his head and comb neat, neck-marking clear, but perhaps a little too much pencilling on saddle. Second we think the Cirencester winner, very good in shape, a little long in tail. Third fine in breadth and cushion; he is too long in shank, and his comb rather high at the back. Fourth a very pretty bird, too dark on the back, but when he stands well up his neck hackle covers this. 352 (Miss Borrow) good, comb a little coarse. 359 (Lady Dartmouth) good in colour and breadth. Pullets.—The first winner is not large, but very good in colour, form, and hackle; her tail feathers beautifully laced. Second a finely grown well-feathered pullet with beautiful neck hackle. Third very large, a little gawky. Fourth as pretty a bird in style and shape as any in the class, but deficient in hackle-marking. Mrs. Crook's very highly commended bird nice but creamy, otherwise she must have been in the prize list. 383 (Mrs. Bain) another good bird; 393 (Watson) nice in shape but tinged; 394 (Dean) small but pretty; 395 (Horsfall) very good, and we thought worthy of at least a "very highly commended;" 399 (Mrs. Wolcombe) the largest bird in the class, but very like a hen about the head. This class was decidedly a good one. In cocks, first of course was Mr. Horsfall's wonderful old bird. We need not again describe him; he stands up so well in his pen that he is always seen to the fullest advantage. We fear he is a little inclined to a yellow tinge. The champion cup was awarded to him, and we thought most deservedly. The second cock is a grand bird, if he were a little shorter in leg he would be better. Third, barring hocks and long legs, our ideal type of bird. His foot-feathering is splendid, and if he could only be cut down a little he would be an admirable cock. The very highly commended bird was good, but spoilt by a yellow tinge. 409 (Mrs. Drummond) a nice bird. 416 (Mrs. Tindal) broad, but with much ssp in the feathers. The first hen was good in shape and every point all round; her tail was a little lighter than we like, and her size small. Second a much larger hen, but too long in leg; in fact, legginess seems the prevailing fault in Light Brahmas. By some error no award of third prize was announced. Mr. Bloodworth's very highly commended bird was good in shape and feathering, but too creamy in colour.

**HAMBURGS** were not striking classes, the Golden-pencils and the Blacks being the best. *Golden-spangles.*—First in cocks a nice bird all round, with good natural comb, not sufficiently marked on wing; he was too timid to show his carriage off in the pen. Second a peculiar bird, good in carriage and very dark in colour, his comb is very narrow for a Spangle; we observed

that his eyes were a little scurfy. Third a pretty stylish bird, we liked him as much as any in the class. The cup for the best Hamburg hen went deservedly to the first Golden-spangle; she is a beautiful bird with most lustrous moons evenly distributed over a rich ground colour. Second another good bird in nice condition, not quite so perfect in spangling. Third fair, with large not very even spangling. The *Silver-spangles* were not very good. First cock a pretty bird with natural not over-good comb, and earlobes tinged. Second a very moderate specimen with splashed tail and yellow hackle. Third the best bird in style and form, he had a little too much white in breast, and had apparently once had a comb too heavy on one side which had been "improved." The first hen was pretty with even mooning all over and not too black in general effect. Second another of the same type. Third too black with spangles running together. *Golden-pencils.*—The cup for cocks went to this breed. The winner is very pretty, beautiful in comb and colour and with a nicely edged tail. Second had a nice honest comb; we do not ourselves like so much contrast as he has between the colour of neck-hackle and saddle. Third a small neat bird, his sickles are black with a curious bronze bar across them. The first hen was good all round and in good condition, her neck-hackle not clear enough. Second out of condition, well barred. Third a fair bird, coarse in pencilling. *Silver-pencils* were, as everywhere now in the south, poor classes. The first cock very yellow but with nicely laced tail. Second and third very indifferent. 541 (Dr. Snell), very unhealthy; we begged the Secretary to have him removed. The first hen was well marked but poor in comb. Second fairly marked with a cloudy hackle. Third nearly white in breast. *Blacks* were well-filled classes; cocks numbered seventeen, and nearly every pen was noticed. Hens twelve. It is unfortunate that a breed like this, of which lustre is one of the first points, should not be placed in an upper tier in the best light, especially so in a place like the Drill Hall at Bristol, where there are so many light positions. Such, however, was not the case, and these classes were in a very indifferent light. The first cockerel was a lovely bird all round, and found a purchaser at the auction; his carriage, comb, and lobes were all perfect, we thought he might be a little more lustrous. Second a very glossy-green bird. Third a smaller bird, also good in colour. Mr. Serjeantson's very highly commended cockerel looked to us a capital one. Of the winning hens the first and third were good in shape and lovely in colour. It struck us they would make a good match. Second a nice hen in comb and colour, a little heavy in tail.—C.

**COCHINS.**—These classes were again on the whole extremely good, the Whites particularly so; in fact we seldom remember to have seen better, and we hope that those who so persistently assert that the breed has deteriorated were at Bristol to see for themselves. The *Bufs* we thought the weakest in quality, while there was an improvement in the Blacks. In Buff cockerels Mrs. Tindal's Palace bird was again first. His colour is very good, but we do not admire his head, still he was well in his place. The second and third were both fine chickens, but both seemed a little faulty in colour. We liked pen 82 (W. A. Burnell), but his wings were also a little tipped in colour; 77 (Mrs. Allsopp) we admired very much. In pullets we did not think the general quality nearly equal to the Palace class. The first was the largest, but the second the best in colour; pen 91 (Capt. Robin) looked very aged indeed. In old cocks we liked the third best; he is full in the hocks, but is a wonderfully well-coloured bird, and has peculiar hackle feathers growing among his fluff. Hens were good, the first capital in colour, large, and shapely; the second was also very good; 115 (Percival), was not of good colour, but of admirable shape. In Cochinchina cockerels we liked the awards; the first was a fine upstanding bird. In pullets the first-and-cup had a look of age about her head; she was well marked. Second and third being prettily pencilled, but only fair in size. In adult cocks the first was good and well feathered; second was nearly equal to him. In hens the winners were all well pencilled and of good size; 161 (Jones) we liked very much, as too we did 159 (Pope). *White* cockerels were capital, the first large, white, and showy; but we preferred the second, which is the first Palace bird; he has much more depth and saddle. Third we did not like; he was the bird we said was "too Pointer-like" at the Palace, and we still think the same. Pullets were admirable, and the winners well selected. Perhaps first and second might have changed places, but they were both good birds. In cocks we liked the shape of the first one very much; the second is the cup Palace bird; the third we also liked perhaps as well as any. Mrs. Holmes's (202) was a grand bird, and of snowy whiteness. Hens were a wonderful lot. There were half a dozen really good, and we liked 222 (Acton Tindal) better than the second-prize bird; the latter looked small and tucked up; 226 (Turner) was very good, but not in feather. In *Black* cockerels the first was we think the Palace bird, looking capital; second a wonderfully showy cockerel, good in colour and symmetry; third also very showy and good; 232 (Storer) was much hooked, or else of marvellous colour, and was a bargain to someone at the reduced

price of 30s. The first pullet had an ugly comb, or else was large and lustrous; second and third both good birds. In adult cocks the first was good all round, very black, broad, and large; second also a capital cock, but wants more time; third very good too. In hens we liked the second best, but all three prize birds were very good. The third had yellow legs, and was claimed for £6 6s. We hope to find the Buffs better at Birmingham, but in many respects the Cochins were up to a high standard.

**SPANISH.**—These were good. The cup went to a cockerel with very good face and in fair condition; it was claimed at the auction for £10 10s. Second also a showy bird, with a good comb and face. In pullets the first came in well, and were well shown; second and third both good; 465 (Jones) we much liked, and 473 (Palmer). In cocks a neat bird was first, only in at £3; he was a bird with a well-shown face. Second very nearly as good, with much quality about him. In hens the cup bird was well to the front, but there were many good birds in the class, and after the winners we much liked Mr. Rodbard's and Mr. Palmer's two birds.

**GAME.**—There was a fine show, the birds being well up in condition mostly and looking well. Both the cups went to Black Reds and both to Stowmarket. In *Black Reds* the first cock was an adult, a capital bird, and well in first; his tail rather coarse, but his colour was very good. Second also a showy bird; third was a stylish and good-coloured cockerel. On going over the class with a Game breeder we thought 584 (Dutton) deserved some notice. He looked like the third in the undubbed class at Oxford, and we have since learnt that the bird was looking poorly when they were being judged, suffering perhaps from indigestion, for he was in good looks when we saw him on the Saturday. In hens the cup bird was very showy and well-shaped, but we did not like her comb; second had much style about her; and the third was a good bird, neat in shape and good in colour. She was claimed at the auction. In *Brown Reds* the first cock was smart in carriage and had a capital head; 607 (Cock) an undubbed bird of good colour. The first *Brown Red* hen was capital in colour, and very stylish; third we liked also, but she was a little small; 619 (Phillips) was also a good bird. In the Variety class a good Duckwing came in first, bright in colour and good in head; second went to another good Duckwing, a bird good all round, and the bird cup at the Palace we believe; third a smart yellow-legged Pile. In hens all the prizes went to Duckwings, and all birds of quality.

**MALAYS** mustered thirty-one pens, and seventeen of them were mentioned. We were sorry not to see Mr. Hinton in person there as well as in feather, for it would have warmed him up this chilly weather to see his old friends so strongly and well represented; £11 12s. 6d. in entry fees, and £8 in prize money. Paying at last are the old loves, and paying well. First a great cockerel—tall, bony, angular; second another almost as tall, as bony, as angular, and in better feather; third narrow in tail, but good in shape. 747 (Brooke), very good indeed. A grand pullet won first in the next class; capital in colour and good in size. Second and third two well-grown birds; true Malays in shape. There were three or four more as good almost, for it was a fine class. Of them we liked 765 (Lowe), 771 (Ridley), 767 (Baker), and 763 (Joint).

**FRENCH** four classes, and all well filled. We are sorry we were unable to give a report of these at the Palace, but up to the last we hoped "D., Deal," would have turned up, but sad to say he did not. In *Houdans* a grand old cock came in first; his crest hardly ready, but his colour good. Second another old bird; large and well-footed. Third a fair cockerel. In hens our old friend came in again first. Her colour is our *beau idéal* of a perfect Houdan hen. After the prize birds we liked 693 (Scott) and 689 (Wood). In the next class the cup went to a large *La Flèche* cockerel, handsome in its ugliness; second a good old *Crève* of lustrous colour; third another adult of good quality. In hens first a *Crève*, large in crest and of massive shape; second a *Crève*, also good in crest and colour; third a *La Flèche*, large and cheap. 730 (Vickery) a large hen of good colour; 729 (Fowler) a square-shaped hen, bright in plumage; 742 (Arnold) a Blue *Crève*, rather peculiar, and certainly handsome, called in the catalogue a "Cindered *Crève*," whatever that may mean. She was the colour of an Andalusian, and made a change among the Blacks.

**POLANDS.**—The Blacks were three ahead in numbers of the Golds and Silvers together. The cup went to a grand *Silver* hen, a bird with a marvellous crest, and of good colour. The second *Golden* hen was a fine one, bright in colour and good in crest. The second *Silver* cock was large, and with a grand crest, while the third *Golden* was another smart bird. In *Black* cocks we liked the winner. His crest is very full, and very large, and very white. We preferred several pens to either second or third, notably so pens 785 and 786, the Palace first and second winners. In hens the first was large in crest, and in very good condition. Second and third might well have changed places, the third being the most wonderful pullet of the colour we ever saw. 798 (Unsworth) was good in crest, and of a good

black colour. This breed has made more progress of late than any other breed we know of, and committees would do wisely to give them classes more frequently.

**LEGHORNS.**—Four small classes. In *Brown* cocks we think the earlobes won the bird first place, as second and third were in almost superior condition. The third bird was our choice for colour. In hens the first was not very bright, but large. One found a purchaser at 63s. Second very light, and generally good. In *Whites* the cup bird was rather small, or else good in earlobes and fair in colour. Second a smart bird with good comb. We thought the first *White* hen also rather small, but in good colour and condition.

**SILKIES.**—The first were perhaps the most even as a pair, the pullet peculiarly good in crest. We liked the second cockerel very much; his comb, too, has improved in colour. The third hen was much hocked, which we look upon as a disqualification, or else her crest and comb were remarkably good. 1019 and 1022 (Ferris) only contained single cockerels. 1023 (Stephens) had a cock with a large crest, but the bird was much out of condition. 1024 (Hudd) a fair pen all round, with moderately good points. On the whole the class was satisfactory.

**THE VARIETY CLASS.**—In cocks a pale Cuckoo Cochin was first, a Sultan of moderate colour second, and an ugly Plymouth Rock third. In hens a good Andalusian was first, a Sultan hen second, and a very moderate Cuckoo Cochin third. These classes we thought not up to the average. The Sale classes we will not mention, as we fail to see their use, and are averse to the system entirely when the prohibitive price does not reach £4 or £5.

**BANTAMS.**—*Reds* were all in one class; the cup pen most stylish and small. In the next class smart *Piles* were first, good ditto second, and pretty *Duckwings* of good colour third. *Blacks* were wonderfully good; the cup pen in grand feather and very lustrous. Second very neat in heads, as too were those in pen 984 (Earnshaw). The *Laced* made an exquisite class. Very beautiful *Silvers* first; good *Silvers* second, much reminding us of the first Palace pen; and deep *Golds* third. 996 (Leno) excellent *Silvers*, the lacing being really perfect. 1001 (Hodson) very good indeed. The Variety Bantam class was small—three prizes and three pens. First moderate Cuckoos; second *Black-booted*, very good indeed bar a few red neck feathers; third the *Frizzles*, with the ugly combed hen. In single Bantam cocks all three prizes went to *Black Reds*.

**WATERFOWL.**—*Aylesburys* only made six pens; all noticed, and all good. First well to the front. In *Rouens* the cup and second again went to Mr. Evans, whose name means quality; third very good in plumage. *Blacks* were nineteen pens strong, and many pens were of wonderful colour and excellence. The Oxford cup pen was first. The drake in the second-prize pen was very lustrous. But of the three prize pens we liked the third best. They seemed most even in colour as a pair; but in the whole class our choice was pen 1081 (Sainsbury). We thought them far ahead; the best in the class. They were the pen we saw at Swindon, and in our opinion, of their being the best pair at the Show, we believe most *Black Duck* fanciers who were present agreed. 1072 (Malden) was empty. In the Variety Duck class a pen of *Mandarins* in charming feather were first. Second went to the different coloured headed birds, which are variously named—viz., Variegated Shieldrakes, New Zealand Shieldrakes, Paradise Shieldrakes, and also rejoice in the name of Tadorna Variegata. Third went to lovely Carolinas. 1096 (Leno) good Carolinas; soon claimed at £4. *Geese* only made five pens. First good Toulouse, second Embdens, third Toulouse goslings. In *Turkeys* the first were well in front of the others. They were enormous in size and very good in colour. 1105 (Lang) were too late, or would have come in third we should imagine. We furnish full awards below, and believe for quality, though not in size, the Show was up to the high standard of former years.

Thus concludes our report of this Show, which was very similar to former shows at Bristol; the food bags in the same places, the arrangement of the classes in the same order, and, sad to say, visitors in their paucity seeming as usual to play puss-in-the-corner in the long and empty avenues. "Why don't the people come?" "Why won't the people come." A few exhibitors, the cheerful Secretary, the feeders, and half a dozen ladies make up the usual number of visitors to be seen at one time. We hope for the best, but we fear this last attempt will be no more a fortunate one than others have been in a pecuniary point of view, for patronise the Show by their presence the Bristolians will not do. As good as usual were the arrangements—well mixed food, coarsely cut chaff to floor the pens, green lettuce and cabbage leaves, all were there.

The Judges were Mr. Smith for Game and Game Bantams; Mr. Hewitt and Mr. Teebay, the latter gentleman taking the Cochins, Brahmas, Hamburgs, Silkie, and some of the Sale classes, while the former took the remainder.—W.

#### PIGEONS.

"We hope you will go to Bristol and report the Pigeons for us as usual; it seems to be your manor." Thus wrote one of

our Editors. So being "my manor" I must of course have a shot over it. And in truth Bristol seems the especial place to, and to have special attractions for, a west countryman. Bristol gives the name to the Channel that divides South Wales and England. As to big cities or great towns to the west of Bristol there are none: Bath "the queen of the west," Bristol "the city of the west."

I did not find the Show quite as large as last year—nearly four hundred pens less; of Pigeons, however, only fifty pens less. But then the birds were as a rule superior; and in Spanish fowls, Bristol's speciality, the birds were better than at the Palace. Would that I could note an improvement in attendance, but, alas! I cannot. The long alleys were empty of company, and seemed to be cleared and ready for children to play ball in. Why is this? Crowds come to the Bath Show. Well, Mr. Cambridge, you must try cats; rely upon it ladies will come and see them, and then get by degrees a higher taste. But leaving cats for inspection another year, all's well, I stand before the Pigeon pens.

**Carriers, Black.**—In both cocks and hens Mr. Maynard took first over Mr. Baker. This in Wiltshire phrase was "being *main-hard* upon Baker." The first-and-cup cock was deserving its place, but the second was remarkably fine in beak-wattle, while the third was a fine-feathered and well-shaped Carrier. The second hen was young and very promising. As to the Duns, the first (Fulton) was a bird of colour, size, and style; second not its equal; third too down-faced, and lower beak-wattle small. The second Dun hen I preferred to the first. The Any other coloured Carriers were of course—for it is, alas! an of course—all Blue, Whites being absent. First cock (Fulton), a very noble bird. The young Carriers were a pleasing lot. First-and-cup cock, a Dun, was of an excellent colour and fine thin neck. The prize hens were all Blacks.

**The Pouters.**—These were a little awkward to find, their pens not coming next or near the Carriers. Black and Blue cocks certainly a good class. First (Watkin) nice limb, colour and shape, but not large crop. Second (Hill) the best blue colour of the lot. Third (Bullen) a Black, very fine colour. No. 1207 had not even a highly commended. Strange this. Black and Blue hens.—First-and-cup a magnificent Blue (Baker). Second and third (Pratt and Baker) capital Blacks. Black Pouters have advanced this year. Red and Yellow cocks.—All save the prize birds were poor. First very good Red. Hens of same colours better. First (Watkin) too heavily flagged for a prize bird, and not a good Red in colour. Second (Hill) a fine Yellow. Third long, but very washy in colour. 1235, Red, highly commended (Fulton), fine globe. 1234, Yellow (Pratt), too grey, but nice long hen. 1236 highly commended, Yellow (Fulton), good. Cocks (any other colour) all Whites.—First a very elegant bird (Watkin). White hens, of course Mrs. Ladd first. I name that bird "The White Empress." An honour to Wiltshire she is, and was very civil to "WILTSHIRE RECTOR," putting on her best manners to me. There was one bird in this class not White, a fine, long, elegant, showy Dun, that took third prize (T. Bullen). Why were no good-feathered and barred Mealies shown? Now dodging back again, please alter this, Mr. Cambridge, next year.

I come to the *Almonds* (cock or hen).—First (Baker) a good old bird. Second (same owner) a nicely spangled bird. Third very good (Beck). A nice and numerous lot of Any variety of Short-faces followed. First a rich Red (Baker) with beautiful eyes. Second a Kite with capital head. Third (Beck) a Red Agate. Among the highly commendeds was a well-shown beautifully coloured Red, though a trifle coarse, No. 1262 (Crane).

**Barbs** (cocks).—Black, Red, Yellow won as to colour and order. The cup hen—what a hen! so very superior. Second and third might have changed places with advantage, I think. Young Barbs.—First and second Black. First fine in head and colour. Third a pleasing Yellow.

Foreign *Owls* more numerous than at the Palace. First and third Whites. Second a good Blue. Two highly commendeds, 1296 and 1297, worthy of prizes.

**The Trumpeters.**—First-and-cup, of course, Mr. Lederer. Second same owner. Third a good Black. Highly commended, 1306 (Hill), a fine Mottle. What strange poke-about, odd, heavy chaps are these Russians! Pity there are no Turkish Pigeons to put next them.

**Jacobins** (Red or Yellow, cocks or hens).—First Red (Fulton), colour, mane, down-face excellent. Second Red (Baker). Third Yellow (Fulton), excellent. I noticed that as a rule the colours in this class were very good, so also the chains, but the hoods would go back or have a break in the centre of them. This fault even more apparent in the Any other colours. Of these, First a White (Fulton), and very good. Second a neat Black (Baker), but too long-faced. Third a White, a little large, but good chain and mane.

**Fantails.**—Only one Blue in the whole lot. First-and-cup (Serjeantson) a fine tail, good shape, but no motion. A Scotchman looking at it would want "a drap of whusky," or at least a pinch of snuff, to recover himself. Second and third (Maynard) two good Whites.

**Turbits** (Red or Yellow).—I really was surprised to see No. 1351 carry off first and cup. Bad washed-out colour (Yellow), poor peak-crest, and stained beak, the face all; while the two Palace first and second (Crafer) here only second and third. Both these rich Yellows and fine peak-crests. I was surprised, and am still. Any other colour.—First a super-excellent Black (Cresswell), worthy of any cup. Second (Wood) a very superior Silver. Third (Salter) a nice Blue. This class very good.

**English Owls.**—First-and-cup a model bird, a Silver (Salter). **Nuns.**—Very very few, only three pens. First Mr. Siddle with a very good bird. Second Mr. J. T. Holmes. I hope he will take up the Nuns and make The Cedars at Bath famous for them. There is a grand opening now for a Nun fancier, and the Judges must encourage Red and Yellow Nuns as well as the Blacks.

**Maggies** a good class. Black first, Black second, Yellow third. Glad to see the Yellows encouraged by a prize. If Judges had been equally considerate to Yellow Nuns they would not have vanished.

**Dragoons** (Blue or Silver) an excellent lot. Whites choice; first (Woods) a noble bird. Any other colour, first (Woods) a Chequer, not good-shaped wattle—not the pig shape; too much lower beak wattle; neck thick. Second a better head, a nice Yellow; third (Sugden) a good Red. Young Blues and Silvers not remarkable. Young, any other colour, first (Fulton) an excellent young Yellow; second (Woods) a good Chequer.

**Antwerps** of different varieties; among the Long-faced some very likely working birds.

Any other variety not mentioned, too small a class.

**Tumblers** (Long-muffed).—First fine colour and marking—a Black Mottle; owner Mapplebeck. Many of the muffs very long. Long-faced Beards and Balds.—Good old sorts; the former once famous in Bristol. Any other variety of Flying Tumbler.—This a capital class, and showed that once let prizes be offered for the true old smooth-legged Tumbler—the Tumbler, many birds will be forthcoming. I like flying men to be encouraged. First a Red Mottle (Mapplebeck), capital bird; second Red (Fulton), a fine whole-coloured Red, as good a bird as I could wish to see, a model of a clean-legged flying Tumbler; third (Hyde) a Yellow Mottle, good colour, neat shape; 1577 (highly commended) Yellow, very nice; 1578 next to it, a whole Yellow, as good or even better. May this deserving class of natural-shaped interesting birds appear at every show.

A flying class for Homing birds, and long classes of selling birds, completed the Show, which, save in visitors, was as a Show all that can be desired.—WILTSHIRE RECTOR.

#### POULTRY.

**DORKINGS.**—Coloured.—Cockerel.—1, O. E. Cresswell. 2, R. R. W. Beachy. 3, R. Burnside. 4, Countess of Dartmouth. *vhe*, Mrs. Hind, Rev. H. F. Hamilton. *Pullet*.—1, S. Newick. 2, A. M. Gibbs. 3, Rev. H. F. Hamilton, 4, Miss J. Milward. *vhe*, O. E. Cresswell, R. W. Beachy, Rev. G. Watson. *Cock*.—1, J. Cople. 2, L. Pilkington. 3, Rev. G. Watson. *Hen*.—1 and Cup, F. Parlett. 2, Mrs. Hind. 3, Mrs. Radcliffe. *vhe*, R. W. Beachy. *Silver-Gray*.—Cockerel or *Cock*.—1 and Cup, O. E. Cresswell. 2, F. Chessum. 3, W. W. Rutledge. *Pullet* or *Hen*.—1, O. E. Cresswell. 2, W. W. Rutledge. 3, H. T. Sotham. *White*.—Cockerel or *Cock*.—1, Mrs. M. A. Hayne. 2, Countess of Dartmouth. 3, R. A. Boissier. *Pullet* or *Hen*.—1, O. E. Cresswell. 2, Dr. E. Snell. 3, Mrs. M. A. Hayne.

**COCHINS.**—Cinnamon or Buff.—Cockerel.—1, Cup, and 2, Mrs. A. Tindal. 3, Henry Lingwood. *vhe*, Mrs. E. Allsopp. *Pullet*.—1, R. P. Percival. 2, A. J. E. Swindell. 3, Mrs. A. Tindal. *vhe*, W. A. Burnell. *Cock*.—1, R. P. Percival. 2, H. H. Tomlinson. 3, G. H. Proctor. *Hen*.—1, W. A. Burnell. 2, W. W. Rutledge. 3, H. Tomlinson. *Brown or Partridge*.—Cockerel.—1, E. Tudman. 2, R. P. Percival. 3, Hon. Mrs. Sugden. *Pullet*.—1 and Cup, R. J. Wood. 2, J. H. Jones. 3 and *vhe*, Mrs. A. Tindal. *Cock*.—1, H. Tomlinson. 2, E. Tudman. 3, R. P. Percival. *vhe*, T. Aspdien. *Hen*.—1, Mrs. A. Tindal. 2, R. J. Wood. 3, W. Nickolls. *vhe*, J. H. Jones. *White*.—Cockerel.—1, P. H. Chase. 2, Mrs. A. Tindal. 3, W. H. Coplestone. *Pullet*.—1, J. Turner. 2, Mrs. A. Tindal. 3, J. H. Nicholls. *vhe*, Mrs. Wilde. *Cock*.—1, Mrs. A. Tindal. 2, R. A. Boissier. 3, H. Tomlinson. *vhe*, Mrs. J. T. Holmes. *Hen*.—1, Mrs. A. Tindal. 2, C. Bloodworth. 3, H. Tomlinson. *vhe*, W. A. Burnell. *Black*.—Cockerel.—1, E. Kendrick, jun. 2 and *vhe*, A. Darby. 3, H. J. Storer. *Pullet*.—1, T. Beardsworth. 2, N. Cook. 3, T. Aspdien. *vhe*, E. Kendrick, jun. *Cock*.—1 and 2, A. Darby. 3, E. Kendrick, jun. *Hen*.—1 and 2, N. Cook. 3, J. Day. *vhe*, E. Pritchard.

**BRAMBLINGS.**—Dark.—Cockerel.—1 and 3, Horace Lingwood. 2, R. P. Percival. 4, Rev. H. F. Hamilton. *Pullet*.—1 and Cup, R. P. Percival. 3, G. S. Pearson. 4, Horace Lingwood. *Cock*.—1, E. Kendrick, jun. 2, J. Lyon. 3, Horace Lingwood. *vhe*, Mrs. Radcliffe. *Hen*.—1, Newham & Manby. 2, Rev. J. D. Peake. 3, T. F. Ansell. *vhe*, T. Beardsworth. *Light*.—Cockerel.—1, P. Haines. 2, R. P. Percival. 3, Horace Lingwood. 4, Mrs. Wollocombe. *Pullet*.—1, Mrs. J. T. Holmes. 2, W. H. Haseler. 3, T. A. Dean. 4, M. Leno. *vhe*, Mrs. Crook. *Cock*.—1 and Cup, R. E. Horstall. 2, Horace Lingwood. 3, Mrs. Crook. *vhe*, G. B. Breeze. *Hen*.—1, F. Holbrook. 2, Dr. G. A. Angier. 3, Mrs. J. Bloodworth. 4, G. B. Breeze. *Hen*.—1, F. Le Sneur. 2, P. Le Sneur. 3, R. A. Boissier. 4, H. SPANISH.—Cockerel.—1 and Cup, F. P. Le Sneur. 2, E. Jones. 3, E. Allsopp. *Pullet*.—1, J. Walker. 2, S. H. Hyde. 3, Mrs. E. Allsopp. 4, E. Jones. *vhe*, P. F. Le Sneur. 5, W. Hawkes. *Cock*.—1, E. Jones. 2, J. Walker. 3, W. R. Bull. *Hen*.—1 and Cup, J. Hunt. 2, E. Jones. 3, Miss E. Browne.

**HAMBERGS.**—Gold-spangled.—Cockerel or *Cock*.—1, T. Dean. 2, W. A. Hyde. 3, G. J. Duckworth. *Pullet* or *Hen*.—1 and Cup, T. Dean. 2, G. J. Duckworth. 3, W. A. Hyde. *Silver-spangled*.—Cockerel or *Cock*.—1, W. A. Hyde. 2, Duke of Sutherland. 3, Duke of Sutherland. *Pullet* or *Hen*.—1, Ashton & Booth. 2, Miss E. Browne. 3, Duke of Sutherland. *Gold-pencilled*.—Cockerel or *Cock*.—1 and Cup, Duke of Sutherland. 2, J. Rawnsley. 3, W. R. Tickner. *Pullet* or *Hen*.—1, W. K. Tickner. 2, Duke of Sutherland. 3, J. Rawnsley. *Silver-pencilled*.—Cockerel or *Cock*.—1, J. Rawnsley. 2, Duke of Sutherland. 3, J. Preston. *Pullet* or *Hen*.—1, J. Rawnsley. 2, Duke of Sutherland. 3, Dr. E. THE BIRMINGHAM COLUMBARIAN SOCIETY'S PRIVATE SHOW, advertised in another column to-day, we hope will be well attended. There are no prizes offered, and all visitors will be welcomed to see the birds which will be exhibited by the members.

He begins, then, with the history of the queen bee—development from the egg to full maturity, including her qualifications for becoming a fruitful mother and the conditions under which she became such. He traces with the most patient assiduity, never taking anything for granted till he has proved it to be an indisputable fact by oft-repeated trials and experiments, varied and modified in every conceivable way. To most of the results which he gave to the world at the close of the last century every body capable of being convinced by positive proof and logical

argument has yielded assent long ago. Of course I speak of the rule which may be said to regulate the proceedings of bees, for since his day there have not been wanting instances of apparently exceptional violations of the established customs and habits of queens. For instance, no doubt it is almost invariable that young queens mate with their drone lovers in the open air. With all his attempts to find an instance to the contrary Huber never had a single demonstration of exceptional conduct in this respect on the part of the many young queens which he subjected to trial. It is most interesting to read the story of his experiments—with what patience he pursued them, taking nothing for granted; for, as he truly observes, “in observations which are both new and delicate, and where it is so easy to be deceived, I consider that a candid avowal of my errors is doing the reader service. This is an additional proof among others of the absolute necessity that an observer should repeat all his experiments a thousand times to obtain the certainty of seeing facts as they really exist.” I cannot help here drawing the attention of whoever it may concern to this modest statement of this really great man—great in his peculiar line of study.

But to proceed. Shall I assert that the first instance of superior knowledge in us moderns allows us to supply exceptions to Huber's rule, to which he knew no exception?—namely, that queens can be fecundated in the interior of the hive, and that it is not necessary for them to leave it for the purpose. We have heard it stated of late years, I think even in this Journal, that it is not necessary for young queens to meet the drones in the open air; but I cannot lay my hands on the evidence alleged, and I must say that I have never been convinced that the data were sound on which this evidence was presumed to be founded. If any readers of this Journal can prove the fact from ocular demonstration we shall all be interested in hearing of it.

Have we anything to say to Huber's discoveries relative to the curious fact which presented itself invariably to him, that if for any reason the impregnation of the queen bee has been retarded for twenty-one days she never can lay any but drone eggs? Again and again by a plethora of experiments this was proved to be the rule, no exception presenting itself to his notice. “My evidence,” he says, “is demonstrative, for I can always prevent queens from laying the eggs of workers by retarding their fecundation until the twenty-second or twenty-third day of their existence.” Our late excellent friend Mr. Woodbury devoted a great deal of attention to this matter, and detailed instances which came under his own observation, which satisfied him that Huber's conclusion on this point, however his experience may establish a rule, cannot be considered as absolute and final. He found that sometimes young queens which had been unable to mate with drones till the thirtieth and even fortieth day after their birth were still able to breed worker bees. Probably this is owing to influences of season and temperature, which develop or retard the queen's physical powers, as we know that in winter time the hatching of eggs is often checked many days, as well as the issuing of the full-grown insects from the cell. We should, I think, be acting imprudently were we to accept Mr. Woodbury's experience as otherwise than exceptional.

The most real and marvellous discovery which has been made about bees since the days of Huber is the fact, which has been proved to demonstration over and over again, that queen bees do not remain barren even if they fail to mate altogether. To Von Siebold, a German naturalist, we are indebted for this surprising discovery, and to Mr. Woodbury for drawing attention to it in England. It is some years since the matter was discussed in the pages of this Journal, and I believe every person disposed at first to doubt its truth ended by a full assent. The fact is that unfecundated queen bees have the inherent power of producing drone bees, but not (in any case known) those of workers. This has been called *parthenogenesis*.—B. & W.

## BEES DURING THE PAST SEASON.

I SEND you an account of twenty-six of my hives—hives that I have not assisted by feeding since the 1st of June.

	lbs.		lbs.
1. Ligurian, swarmed, nadired with bar hive	99	13. Black swarm	45
2. Black, swarmed once	57	14. " "	44
3. Ligurian, swarm returned	80	15. " "	50
4. Ligurian, swarmed once	80	16. " "	55
5. Black swarm	58	18. Accidentally no return: destroyed.	
6. Ligurian swarm	52	19. " "	
7. Black swarm	42	20. Black swarm	38
8. Ligurian, swarmed	80	21. Hybrid, swarmed twice	80
9. Black swarm	44	22. Black swarm	52
10. " "	35	23. " "	49
11. " "	45	24. " "	60
12. Hybrid, swarm returned, nadired, with bar-frame nadir	90	26. " "	35

I have introduced during the months of October and November twenty-four Ligurian queens; and as I have sixteen straw skeps, all black bees, besides those I have numbered, I may make a trial next year.

My straw skeps are all small (12-inch), swarmed this year, and weigh from 30 to 40 lbs. each. I sent six to Manchester last month, their average was 33½ lbs.; also one Ligurian, 39 lbs. Four of them were broken on the railway. I shall not sell any now to go that distance, but may do so in the spring, when the risk is not so great.—JAMES HALE, *Kedington, near Haverhill, Suffolk.*

## OUR LETTER BOX.

HOUDANS (B. E.).—There is no book devoted to them.

GLUTEN (G. Fenn).—If wheat flour be kneaded into a paste with a little water it forms a tenacious, elastic, soft, ductile mass. This is to be washed cautiously, by kneading it under a small jet of water till the water no longer carries off anything, but runs off colourless; what remains behind is called gluten.

DEAD HIVE (*Senex Corycius*).—We do not trace in your account of the mishap of your deserted hive any of the known symptoms of “foul brood.” Your bees have succumbed probably to natural decay after the loss of their queen from whatever cause. We know well the sort of mildew condition of the pollen as described. It merely resulted from damp causing its decay. It would be likely to occur in an empty hive during such a warm damp autumn as the last. The hornets were probably queens which found the empty hive a snug place for hibernation.

PERFORATED ZINC (H. J.).—You can obtain the  $\frac{5}{16}$ -inch perforated zinc at any ironmongers. Mr. Phillips says, “The great benefit obtained by using it is the prevention of the queen from ascending into the super, whilst the perforations are large enough to permit the ingress of workers without pollen in their baskets. The sheet of zinc, of course, intervenes between super and stock.”

WHERE IS THE HONEY FOUND?—Will those apiarians who obtain large honey harvests have the kindness to give, for the benefit of less experienced bee-keepers, a short topographical description of the country, and the kind and quantity of the principal honey flowers contained within a circle two miles in diameter, having their apiary for the centre?—P. B. P.

## REMARKS.

- 29th.—Slight frost, but fine morning; splendid forenoon, and fine all day.  
30th.—Very dark and thick in the morning, dull all day, and wet night.  
Dec. 1st.—Very fine morning, dull afternoon, and wet evening; wind high at night.  
2nd.—Fine till near noon, and very warm; rain in the afternoon and in the evening.  
3rd.—Rainy morning, raining at intervals more or less all day, very heavily for a short time about noon, barometer falling rapidly.  
4th.—High wind during the night and till the afternoon of the day, when it lulled a little; starlight at 8 p.m., lunar halo at 10.55 p.m.  
5th.—Boisterous, dark, and rainy nearly all day.

A week remarkable for an extremely low mean barometric pressure, and for excessive rainfall. The pressure at 11 a.m. on the 4th was only 28.364 in., being with two exceptions the lowest reading for fifty years. Rain has fallen on every day, the amounts being large but not excessive.—G. J. SIMONS.

## COVENT GARDEN MARKET.—DECEMBER 6.

BUSINESS is so very quiet, and the weather so bad, that there is no report to make.

From observations taken near London during forty-three years, the average day temperature of the week is 45.9°; and its night temperature 33.5°.

## PRUNING VINES.

HERE are more Vines pruned in December and January than during all the other months of the year put together. Amateurs with one or two vineries have mostly cut all their Grapes by this time, and all Vine wood of any importance should have been ripe some time previous to this. When the wood is thoroughly ripe and the leaves off there is nothing to be gained by delaying pruning, and the sooner this operation is performed and the Vines cleaned the better. To the experienced Vine-pruning is a simple-enough matter, but even amongst professional gardeners it is considered very particular work, and in many places pruning the Vines is about the only work the head gardener will not entrust to his foreman or any subordinate. Admitting that Vine-pruning is of so much importance, amateurs must surely often have much difficulty in performing it properly, and a few words of advice on this subject may be of help to many about this time. I will, therefore, briefly give a few practical hints to render the practice as simple as possible.

In the first place, do not think of pruning until all the leaves have fallen of their own accord. Do not pull them off or attempt to cut away the branches when they are green. In some cases the base of the shoot will be quite hard and brown when the point is green. In Muscats especially this is often the case, and very often such shoots will not ripen up to the point, particularly so far on in the season as this. I have seen a good many Vines pruned in this state, but I cannot remember much evil resulting from it; and if the wood is thoroughly well ripened at the base a small green point here and there need not be looked on as harmful. Young Vines in robust health should be closely pruned; but in every instance it is always safest to leave two eyes on each spur, because one may get rubbed off, and when there is not another to take its place there is a blank left in the rod, as well as a loss of fruit.

Old Vines which do not start into growth freely should always have about four eyes or buds left on each spur, as those furthest out are always sure to start if the back eyes do not, and when they do the front buds can be rubbed off; so that the spurs are kept shorter than they otherwise would be.

Young canes planted in spring must be shortened-back to about 2 feet from the ground. Those planted last year, and which have made strong growth this season, will be capable of bearing a few bunches next year, and with this intention from 5 to 7 feet of main cane must be left to each root.

Vines which have been planted for several years and are in fruiting condition part of the way up but not quite to the top will have one leading cane at the top. This must not be left too long, or the rods will be long and small instead of being thick and substantial, as is generally the case when only from 3 to 4 feet of young wood is left at the point each season.

No. 820.—VOL. XXXI., NEW SERIES

Vines in pots do not generally need much pruning, but when they do throw out small shoots these must all be cut off before the Vines are either used for planting or fruiting. In all cases pruning should be done with a very sharp knife, and the shoots must not be broken, split, or twisted, but cut clean through, and in doing this care must be taken not to rub off the buds, which is very easily done.

Many people think it is not worth while using anything to prevent bleeding after the Vines have been pruned, but this is a mistake, as they often lose much strength through bleeding, but sometimes not so much at the time of pruning as when they begin growing, and the cuts should all be dressed with Thomson's styptic.—VITIS.

## DECIDUOUS TREES AND SHRUBS.—No. 5.

STANDARD SHRUBS.—Some shrubs when old are too spreading or straggling in growth to be admissible in geometrical, and especially in small, gardens. Many, especially evergreens, have been found to form compact ornamental heads trained up with straight stems. The utility of these miniature trees in small gardens is at once apparent, and they are very appropriate in formally-arranged gardens. Planted in borders of low-growing shrubs these standard forms occurring at suitable intervals are very effective, and at the back of borders of flowering plants much of the monotonous flatness may be relieved by their introduction.

The number of deciduous shrubs suitable for standards is small. The finest and at the same time one of the hardiest of all variegated shrubs is the variegated Dogwood (*Cornus mascula variegata*), which succeeds admirably in moist soil. *Cotoneaster Simmondsii* is usually considered evergreen, but with me loses its leaves in winter. It is very handsome, its large orange-yellow berries are bright in early winter onwards, and it is very hardy, doing well in any light soil.

*Cytisus elongatus*, *falcatus*, *nigricans*, and *sessilifolius*, all with yellow flowers in early summer, do well in light soils, and being very beautiful deserve a place in every garden. *Genista purgans*, also with yellow flowers, is very attractive. Brooms make pretty standards, especially the Spanish (*Spartium junceum*), yellow; and Portugal (*Genista multiflora*), white. *Forsythia viridissima* has very handsome yellow flowers, which come before the leaves, and is very hardy; and Lilacs, especially the Persian (*Syringa persica*), are very fine; and few subjects appear to greater advantage than flowering Currants (*Ribes sanguineum* var. *album*, *aureum*, and *atro-sanguineum*).

WEeping TREES.—These are becoming somewhat too common in gardens and ornamental grounds, though there is no denying their appropriateness for cemeteries, and for variety their forms occurring among other trees are pleasing. They never appear to such advantage as when planted upon grass. Ash (*Fraxinus excelsior pendula*) is a fine well-known tree for arbours, the gold-barked Weeping Ash (*F. excelsior pendula aurea*) being very distinct and exceedingly ornamental.

No. 1472.—VOL. LVI., OLD SERIES

Acacias in their weeping form are very picturesque trees. *Robinia Pseudo-acacia pendula*, however, requires shelter. The most graceful of weeping trees is *Gleditschia Bugoti pendula* (Weeping Acacia), but it also requires a sheltered situation. Weeping Beech (*Fagus sylvatica pendula*) forms a pendulous pyramid, having a fine effect, and does well in light and chalky soils.

The Rose-flowered Chinese Weeping Cherry (*Cerasus chinensis pendula*), and the weeping form of Bird Cherry (*C. Padus pendula*), may be mentioned along with the Weeping Rose-flowering Thorn (*Crataegus rosea pendula*), and Weeping Laburnum (*Cytisus Laburnum pendula*), as fine-flowering trees of moderate growth; also the Weeping Variegated Thorn (*Crataegus oxyantha pendula variegata*). I have already on page 462 mentioned the weeping forms of Willow and Birch, to which may be added as suitable for moist ground the Weeping Aspen (*Populus tremula pendula*).

Few weeping trees are more conspicuous by their flowers in summer and berries in autumn than a well-formed head of Weeping Mountain Ash (*Pyrus aucuparia pendula*). The Weeping Lime (*Tilia europæa pendula*) is noble in its every aspect, but it does not succeed in an exposed situation, which applies generally to weeping trees, but to this in particular. The Weeping Oak (*Quercus pendunculata pendula*) and the Weeping Walnut (*Juglans regia pendula*), are fine pendulous trees of large growth, both requiring good soil.

In Elms we have some noble pendulous trees, the palm being borne off by the Camperdown Elm (*Ulmus montana pendula* var.), and the fine silver-edged foliage of *Ulmus campestris pendula elegantissima* may be noted as very beautiful; but this with the *Ulmus campestris viminalis variegata* is not very free in growth, appearing to require sheltered situations.

There is a Nut with pendulous shoots—namely, *Corylus avellana pendula*, very pretty, and a Weeping Almond (*Amygdalus communis pendula*). A pendulous Horse Chestnut (*Æsculus or Pavia pendula*) shall close my notes on weeping trees, which I will dismiss with the observation that their rounded heads are desirable for affording variety and breaking and softening lines that would otherwise be abrupt and hard.

Trees named as suitable for standards are equally desirable as dwarfs in ornamental grounds where they have no hindrances to their branches reaching to the ground. I have omitted some trees which I now wish to note—namely, *Acer Negundo variegata*, the most beautiful of all variegated trees, having its Ash-like leaves effectively variegated with white. It is effective in the foreground of dark-foliaged trees, and very useful in flower gardens. Unfortunately it does not succeed in a cold exposed situation, and does best in light soils, though I have seen it very fine in moist soils and sheltered situations. 15 to 20 feet.

Catalpas are seldom seen. *C. syriaca* is a very fine-flowering tree, having white and yellow flowers in July or August; its variety *aurea* having yellowish leaves and flowers. Bunge's Catalpa is the finest of the genus; it (*C. Bungei*) forming an umbrella-shaped or half-globular head of massive bright green foliage; it is very suitable for display upon grass. 15 to 20 feet.

*Ailanthus glandulosa* can only be mentioned as being a handsome tree where it succeeds, but it does not do so in a cold situation; yet in a fairly sheltered place and in well-drained soil flourishes admirably. 20 feet.

*Euonymus europæus* (Spindle Tree) is very hardy, but only handsome from the bright colour of its fruit; the white-fruited variety (*E. europæus fructu-albo*) being very ornamental. The opening capsules are suitable for bouquets. 10 to 15 feet.

*Sophora japonica* in its finest form—namely, *pendula*, is very beautiful, flowering in August onward. In other than sheltered situations it does not succeed well, being cut by frost, but grows freely again from the ripened wood. In well-drained soil it is most likely to do well. 12 feet.

SHRUBS.—For certainty of withstanding winds whether from sea or land nothing can excel the common Elder (*Sambucus nigra*), and it luxuriates in smoky town gardens. It is too common for gardens, and even shrubberies, but it may be useful for purposes of shelter. The Scarlet-berried (*S. racemosa*) is from its clusters of red berries very ornamental in late summer; and the Variegated Silver-striped (*S. nigra variegata*), and Gold-edged (*S. nigra aurea*), with the Cut-leaved (*S. nigra lacinata*) are worth a place in shrubberies. 8 to 12 feet.

Snowberry (*Symphoricarpos racemosa*) is noticeable from its twiggy spreading growth and very beautiful white berries in

autumn, and will grow almost anywhere, even under trees. *S. montana* has small leaves, and does well on high ground in peaty soil. The Variegated (*S. glomerata variegata*) is perhaps a little more select, but because some plants grow freely anywhere and anyhow they are in small request. 4 to 6 feet.

Sea Buckthorn (*Hippophaë rhamnoides*) is very ornamental in wood, having a fine silvery aspect; its yellow flowers are not remarkable, but its clusters of amber berries are very ornamental in late summer and autumn; to secure these it is necessary to plant male and female trees. It succeeds well in sandy soils or others on the coast, where it grows much taller than inland. In high and exposed situations it does not attain more than a few feet in height, but in favourable situations 10 to 12 feet.

Dogwood, after the leaves have fallen, has from its rich red twigs a very striking effect, especially in wet ground and in association with water. The Red (*Cornus sanguinea*) is very fine, of which there is a deeper-coloured variety—*atro-sanguinea*. The Siberian Scarlet (*C. sibirica*) is even finer. The Dogwoods seen in their leafless state across water are simply grand; but it is masses that tell, and not dabs of colour by isolation frittered into nothingness. I have before mentioned the very beautiful Variegated Dogwood (*C. mascula variegata*) as being as beautiful in foliage as the others are in the colour of their bark. The trees do well in any soil, but like it strong and moist. 8 to 10 feet.

The Purple Filbert (*Corylus avellana purpurea* or *atropurpurea*) has leaves as dark and rich as the Purple Beech, and is very effective; the Cut-leaved Filbert (*C. lacinata*) is also attractive. They do well in high or low situations when free from stagnant water in the soil. Tamarisk is very valuable for coast-planting, but inland it is of doubtful hardiness. The French (*Tamarix gallica*) is more tender than the German (*T. germanica*). They have a neat feathery appearance. 6 to 8 feet.—G. ABBEY.

#### A MINIATURE ORCHARD.

"I HAVE a piece of ground 150 yards long and 40 yards wide—a kind of valley, sloping from the centre to the sides. My house is in the centre of the valley. The ground is good and well drained, and I desire to occupy it with miniature fruit trees which will look well and yield fruit, principally for market purposes. I should like an equal number of Apples, Pears, and Plums. I am advised to plant the trees 6 feet apart in the following fifty varieties, which are recommended as being the cream of a good catalogue. My view is that fifty varieties are too many, and I should be glad to have such advice as could be rendered through the Journal, and which would also probably be useful to other amateurs."

The following, from one who has had experience in fruit-growing, is in reply to the above letter.

Had you sent a copy of Mr. H—'s letter to half a dozen of your correspondents you would have received as many different replies, and probably not two of them would have been alike. This proves that there is yet much to be learned on the question of useful fruits, and that discussion on the merits and peculiarities of different varieties is still needed. But although all the replies would almost certainly have differed from each other in the choice of sorts, yet I think all would have agreed, when considering the object in view (an orchard to "look well" and produce fruit principally "for market"), that "fifty varieties are too many."

For myself I should reduce the number considerably, even to the extent of excluding forty of them, retaining only ten. Others might not advise the exclusion of so many, or, if they did, might not retain the ten of my choice. My view is that first of all if the trees on the sloping sides of the valley are to "look well" from the residence they must be planted in rows, each being of one variety. I presume that a walk will lead down the centre of the fruit garden or "miniature orchard," and in that case I should plant the front rows on both sides of the walk with the same variety, choosing Cox's Orange Pippin Apple. This is a compact-growing free-bearing variety, and the rows would not only "look well," but the fruit would sell well in the market. The next two rows—that is, one on each side and at the back of the Apples—I would also have the same, choosing Rivers' Early Prolific Plum, the trees of which would also "look well," and the fruit would sell well. The third rows on either side I would again have Apples—one row of Lord Suffield and one row of Dumelow's Seedling, which I consider as being about the best of early and late culinary

Apples. The fourth row on each side I would have Pears—one row of *Bûre de Capiaumont*, and one of *Bergamotte Esperen*. The former is a very compact grower, free bearer, and a good market Pear; the latter being one of the best and most hardy of late varieties. The fifth rows on either side I should have Plums—one *Victoria*, and the other *Mitchelson's*, both great bearers; and the sixth and last rows on both sides (the back rows) I should have Pears—one *Louise Bonne of Jersey*, and the other *Bûre Die*. The former is a Pear of great excellence, and the other is of great size; both are good bearers, and are "run after" in the markets. I have thus named four rows of Pears in four varieties, four rows of Apples in three varieties, and four rows of Plums in three varieties, making ten varieties altogether.

I should plant fifty trees in each row, which would be about 9 feet apart; the rows also being 9 feet apart, which, having the outer or back rows at 6 feet from the boundary, would afford ample room for a central walk. Each tree in a space of 9 feet would have room to develop itself, and form a useful and handsome specimen. I do not believe in pigmies, and any extreme crippling process to make and keep them so. No doubt there are hunchback slaves who are useful, and stunted animals which are serviceable; but I have a decided preference for stout development and good form in man, horse, or tree, as such I believe are the most profitable.

I will assume in an arrangement like the one proposed by Mr. H—that few will dispute the wisdom of planting each row with the same variety of fruit. If otherwise the orchard would have a "dotted" and unlevel appearance, and would not "look well." Also by having at least fifty trees of a sort there would be a sensible bulk of produce to send to market. Further, by limiting to a few sorts, care and labour in storing and keeping the fruit separate is minimised. Not many experienced growers will, I think, find much fault with the plan, but they may differ considerably in the selection of varieties. Now, it occurs to me that these differences if expressed might be very useful, and I am constrained to ask of those who may dissent from the selection here given—What varieties would you select instead, and why? I ask this question frankly, and with a desire for information for the many who are concerned in fruit-growing. By judging of the merits of varieties of fruit for forming the most profitable rows of fifty trees in each, it occurs to me that we grapple with a question of great importance. It is not what is termed a toy or fancy question, but a matter bearing directly on the fruit supply in its broad and most useful aspects.

I felt that in replying to the above letter that I had a difficult task before me, and I confess to a feeling of wishing the letter had been sent—well, anywhere but to me; yet, as I did not feel at all disposed to shirk the matter, and as I trust I shall never be unwilling to render my mite of assistance as leading to a better supply of useful fruit—profitable to the producer and advantageous to the consumer—I made the best selection that occurred to me. The question is this: Given twelve rows of trees, fifty in each row, of Apples, Pears, and Plums, what sorts would you plant to be most profitable?

Replies to that question could not fail to be useful, even to Mr. H—, whose letter I have quoted, for I have not quoted it all. It contains a postscript, and a very sensible one, in the following words:—"P.S.—I do not intend planting this season, but my plan is to manure the ground and work it well, to take a crop of Potatoes, which I find to be a good 'cleaning' crop, and plant the trees next autumn. My object is to obtain the best information I can in good time, so that I can give notice to my nurseryman to supply me with good trees, and to leave him without an excuse for sending them either inferior as to quality or untrue as to names."

I shall be much surprised if such wise caution and thoughtful preparation do not lead to success.—A MIDLAND COUNTIES FRUIT-GROWER.

### WINTER LETTUCES.

I HAVE noticed lately that the subject of obtaining a good supply of this very useful vegetable (which I am glad English people are beginning to find out is not poisonous in the winter months) has been ventilated in the Journal. I have for many years used, greatly to my satisfaction, for this purpose Looker's acme frames. They are very little trouble, and all through the early spring months they have afforded me a good supply of clean good Lettuces. The cleanliness is a great point, for out of doors it is almost impossible to have them clean. My

frames have remained in the same place for years; and immediately after the Lettuces are pulled I put on some manure and dig it in, removing the glass, but allowing the sides to remain. I either leave it fallow during the summer or prick out Celery into it, to be removed as soon as the plants are fit for the trenches. The Lettuces that I use for winter are *Vilmorin's White*, *Sutton's Commodore Nutt*, and *Wheeler's Tom Thumb*, none of them being so ready to run as the old *Hammersmith*, which is, however, very hardy. I have often wondered that these frames are not more used, especially in small gardens, for they are useful for a great many purposes and are neat in appearance.—D., Deal.

### A GARDEN OF HARDY FLOWERS.—No. 3.

VERY numerous are the gardens in which space cannot be afforded for such a border as was described in page 440, but there is not one garden, however small it may be, wherein a selection of the best flowers might not happily be introduced. It is surprising how much may be done by turning every patch and corner to account. In many a small garden it is customary to convey all the mowings, sweepings, and general refuse to a rubbish heap in some out-of-the-way corner, behind some such screen as a shrub border affords. Access to this corner is gained by a path winding among—often beneath—the branches of the shrubs. In so confined a space even this walk looks inviting, especially in the hot summer days, but it is of course avoided. Now suppose we turn this rubbish heap to its legitimate purpose of enriching our borders, and convert the corner into a cosy little fernery; fringing the sides of the walk too with Ferns, concealing the enclosing wall or fence with Ivy—not all of one sort, but with a mixture of several—and shall we not add a charm to the garden which very few would fail to appreciate? If Ferns are cared for very much we may extend our collection by converting the wall itself into a fernery. There are many ways of doing this; but the most simple and best plan is to drive a few stout staples into the wall, to which some common wire netting can be fastened with wire, keeping the netting about 6 inches from the wall, packing the intercedent space with moss and rough leaf soil, and we have a model fernery in which most Ferns will flourish. Nor need we confine it entirely to Ferns, for we may readily impart variety by the introduction of such *Sedums* as *Sieboldii* and its variegated form, with such other plants as the common and golden varieties of *Moneywort*, *Oxalis corniculata rubra* for its dark foliage, and *Oxalis Bowiei* for its fine crimson flowers. With a little contrivance and management of the soil there need be no difficulty in cultivating many other plants upon our wall, and which I hardly need select, as my readers will all have their own especial favourites; and I have no wish to dogmatise, but would rather point the way and leave each one to turn my hints to account in accordance with the promptings of fancy or taste.

Thus much for the Ferns and the fernery to which I have unintentionally strayed; and it occurs to me, before I revert to those perennials which we cherish for the beauty of their bright flowers, that it may be well to note here a few really choice Ferns that are not much known, but which are so distinct and striking as to merit general attention. The first of these is *Lomaria magellanica*, the Falkland Island Fern, to which I drew attention very lately as flourishing so well in the rock garden at Newick Park. The pinnate fronds are remarkable for their stout texture, stately appearance, the glossy green upper surface of the pinnae, and the deep pink hue of the sturdy stems. The *Ostrich-plume Fern*, *Struthiopteris germanica*, is another fine hardy Fern with most elegant frondage that in old plants grows fully a yard high; these tall but sterile fronds, springing up around the crown in a circle of singular precision, enclosing an interior growth of comparatively dwarf fertile fronds; the entire plant presenting a striking and most ornamental appearance. Another Fern having this interesting characteristic of producing fertile and sterile fronds is *Onclea sensibilis*. It is a distinct and most desirable species, especially adapted for moist damp situations, putting forth creeping stems which spread underground with considerable rapidity. *Adiantum pedatum* with fan-like fronds, and the more common form of *Maiden-hair Fern*, *A. Capillus-Veneris*, are also very distinct and good. Without entering further upon descriptions I may strongly commend *Woodwardia radicans*, the two *Osmundas*—*gracilis* and *spectabilis*, and *Cystopteris bulbifera*. I would also here draw especial attention to the value of *Selaginella denticulata* for clothing with its

mossy yet free growth bare spaces under trees. Amateurs are often puzzled how to dress such spots, yet here is a plant most common in the greenhouse and conservatory, yet it is perfectly hardy, thriving best in drip and shade, and is certainly no unworthy rival of the Ivy which is almost always used in shady places.

Turning now to the thought which induced me to write this article—the want of space for a border of perennials, I am led to the conclusion that if I have a fernery behind shrubs I can just as readily have bright flowers in front of them. Not all along the front, our space is perchance too restricted for that; but can we not gain space for clumps and patches by cutting back or re-arranging the shrubs at one point and removing a strip or two of turf at another? Most certainly we can; and if we cannot have many varieties we can surely have a few of the very best; and by devoting especial attention to their culture we may derive as much or even more pleasure from them than is often had from an extensive collection left very much to take its chance. And this leads me to a subject of especial importance to amateurs, and to which I will allude on a future occasion.—EDWARD LUCKHURST.

### NATIONAL ROSE SOCIETY.

#### CONFERENCE OF ROSARIANS AT THE HORTICULTURAL CLUB.

WHAT may be termed “the power of the Rose” was never more fully exemplified than by the gathering together of professional and amateur cultivators on Thursday last the 7th inst. One cannot conceive it possible that any other flower, native or foreign, could have commanded a response so numerous and influential as the assemblage in question. The summons convening the meeting stood on its own merits, and was not backed with a list of influential names. It was an invitation for devising some satisfactory arrangements as to the future of Rose shows, and to discuss the question as to the formation of a National Rose Society. That was a sufficiently tempting programme, and the large room was crowded with representative growers from various parts of the country. Neither was it a social gathering wholly—a pleasant opportunity for an interchange of greetings by the members of the great Rose fraternity. It was that of course, but much more than that, for the tone of the meeting was decidedly of an earnest business character; and the excellent Chairman had little difficulty in concentrating the discussion to a few practical matters of a fundamental nature relative to the establishment of a Society on a sound basis, and making sufficient provision for its successful management. Everyone assembled was, as Mr. Camm put it, “tremendously loyal” to the queen—the Rose, and the one object of the meeting was to extend, improve, and encourage its superior cultivation. Amongst the company we noticed Revs. Canon Hole, J. T. Boscawen, H. H. Dombrain, C. H. Bulmer, J. B. M. Camm; Capt. Christy, Cranston, G. Paul, Dr. Hogg, Dr. Masters; Messrs. Macintosh, Noble, Cant, Laing, Turner, W. Paul, Adams, Baker, Prince, Cutbush, Curtis of Chatteris, Rivers, Cator, Mayor, Dickson of Covent Garden, Killick of Maidstone, Scott, Robinson, Mayos, Tootell, Mawley, Roberts, Ball, Maurice, Young, Bensted, and A. Paul.

The meeting was convened for two o'clock, but after waiting for some time for the arrival of the Rev. Canon Hole, who by general assent was chosen to preside over the proceedings, the Hon. and Rev. J. T. Boscawen was requested to occupy the chair, and assented on the condition that he was a provisional chairman pending Mr. Hole's arrival. Dr. Hogg was placed in the vice-chair. The Chairman proceeded at once to business by requesting the Secretary to explain the origin of the meeting and to state the objects of its promoters.

The Rev. H. H. DOMBRAIN, who was warmly received, stated that few, on considering the past and reflecting on the present circumstances influencing Rose shows, also in thinking over the future, could consider the prospects as otherwise than gloomy. The Alexandra Palace for the present might be regarded as dead; the Westminster Aquarium as dying—that is, so far as regarded horticultural exhibitions, none of which he believed would be held in the building next year. The Royal Horticultural Society was in a doubtful position; and the Crystal Palace shows were not what they once were, inasmuch as the time of the shows had been extended to two days, while the prizes had been restricted. Neither of these changes could be countenanced by growers and exhibitors, for both of them had a discouraging tendency. The position, therefore, of Rose-growers was gloomy, and hence he communicated with some of them, suggesting the desirability of taking matters into their own hands by way of effecting some substantial improvement. He had had many replies, one from Mr. Baker stating that the formation of a National Rose Society had been already proposed at the festive

board of Mr. Cranston at Hereford, and to which proposal Mr. George Paul had promised his assistance and support. He had received letters also from Mr. Hole, Mr. Turner, Mr. Prince, and many others. The favourable views of his many correspondents, and the suggestions he had gathered from their letters, led him to decide that the time was opportune for the holding of a Rose conference in London to decide on such resolutions which might be deemed necessary for furthering the object in view. He therefore by circular and through the gardening press invited the presence of rosarians at the Horticultural Club. He had received many letters of apology from friends unable to attend the conference, but an encouraging unanimity was expressed by the writers as to the desirability of forming a National Rose Society, and an equal unanimity as to the objectionable nature of two-days shows. Mr. Dombrain then earnestly expressed his thanks for the confidence reposed in him, was deeply gratified with the splendid response of the present meeting, and was sanguine that the deliberations of a body so earnest and influential would result in placing the Rose in a more worthy position than before. The speaker was loudly cheered.

Rev. Canon HOLE now entered the room, and met with hearty expressions of welcome, and he occupied the chair, which was promptly vacated by Mr. Boscawen. The Chairman thanked the meeting for the proud position in which they had placed him, and the more so as the honour of presiding over them was on his part quite unexpected. He thanked especially his esteemed friend Mr. Dombrain for taking the initiative in a matter which was so interesting to all who were present and to many who were absent. He felt the present to be the most auspicious event that had happened in his Rose career since his connection with the “old Society.” He had always thought the giving-up of the old National Rose Society was a mistake. That Society was well established, and successful shows were held. Most people were satisfied, but a few were, perhaps, overworked and became languid, and their Society was handed over to the Royal Horticultural Society. That was not a happy alliance, for the Rose Society became a mere postscript to the R.H.S.—a position which he and many others were not satisfied with, as being too humiliating for the flower which they all cherished so highly. He was happy, therefore, in the fresh start now made to place the Rose in a better position, and he now had great hopes of a really strong representative society being established, and grand shows and general encouragement would follow as the result of their united efforts. He regarded the meeting, however, as one of work rather than words, and would at once call on Rev. C. H. Bulmer of Credenhill, Hereford, to propose the first resolution.

Mr. BULMER, who met with a gratifying reception, said that it would ill become him in taking up the time of horticulturists by theorising, or still more dogmatising, on the subject before them; he would simply narrate his experience, and throw out an idea which he thought was deduced from past transactions and past failures. He had the privilege of following the lead of the Chairman in the campaign of 1858 in connection with the National Society, which held its great Show in St. James's Hall. That Society had failed. He had for ten years been the Honorary Secretary of the West of England Rose Show—a Show which had become widely popular, and which was connected with a generally good and strong Society; but in that Society defects existed which occasionally gave the managers much trouble. He did not feel it necessary to particularise these defects, for he believed that they and all shortcomings might be averted by establishing or reviving the National Rose Society as a high central and administrative authority, the influence of which would be far-reaching and generally beneficial. He believed that a strong, practical, and influential society, such as the present meeting was competent to establish, would be a society of which the country would be proud, a society at once authoritative and permanent, and of the utmost importance in the Rose-loving world. To this end he moved the first resolution, “That the National Rose Society be revived.” This was seconded by Mr. Turner of Slough.

The CHAIRMAN, before putting it to the meeting, suggested that the wording of the resolution should be altered by substituting the word “Show” for Society, but

Dr. Hogg thought the Society should be established first, and a national show would follow as its most important expression, which being generally assented to, the resolution as first proposed was passed unanimously.

The CHAIRMAN then requested Mr. Dombrain to give a sketch of the ideas of the promoters, from which the meeting might be able to frame and adopt further resolutions.

Mr. DOMBRAIN stated briefly, the idea was that a National Rose Society should be formed, and that local societies should be affiliated with it, London being the Rose centre. That the first Show of the Society should be held in London, afterwards having Shows in other places as might be determined on, but wherever the Society's Show is held it must be considered as the Show—the Rose Derby of the year. That the Show should be a Rose Show wholly, no plants being in connection with it, and no music. That the first Show should be held in

St. James's Hall, and subsequently in such places, as Hereford, Manchester, Birmingham, Exeter, &c., as might be arranged, the place selected, of course, providing a guarantee fund to meet necessary expenses.

The CHAIRMAN now asked that a proposition be made, when Mr. GEORGE PAUL proposed that the Society's first Show should be held in London, which was seconded by Mr. Baker, who observed, however, that a Show should be held in London every year.

Rev. J. B. M. CAMM thereupon proposed that one Show be held in London every year, and that it be held at St. James' Hall or Willis's Rooms in June—"Oh! Oh!" from the northerners.) Mr. Camm observed that country shows generally betray failure more or less in some form, and instanced Hereford, where the largest balance ever forthcoming was *4d.* [laughter.] He proposed, therefore, one splendid Show in London every year, with large prizes.

Mr. BULMER was in favour of the Shows being itinerant.

Mr. KILLICK, Maidstone, suggested the holding of one Show in London, and giving aid also to one country show, to which Mr. Baker agreed.

Mr. G. PAUL was also in favour of giving assistance at once to some local shows, so as to spread the influence of the Society as widely as possible. He would say, Let the London Show be grand, but assist also the affiliated societies.

Mr. TURNER said his policy was to do one thing at a time, and do it well.

Mr. DOMBRAIN thought it would be wise to decide on having the first show in London, and leave the question of succeeding years, and afterwards be guided by such experience as would be gained. This view of the question was supported by Mr. Turner and Mr. Cant, and a resolution to that effect was cordially agreed to.

Considerable discussion took place as to the best site for the Show, the Agricultural Hall, Regent's Park, Willis's Rooms, and St. James' Hall being named, and eventually St. James' Hall was decided on, to be secured for July 1st or June 28th. The Chairman here created some amusement by producing a bill in which in gigantic red letters the National Rose Show would be held in the St. James' Hall on July 1st, an old bill of the Show of 1858, which Mr. Camm proposed should be photographed.

The next subject, that of members' subscriptions, gave rise to much earnest discussion.

The CHAIRMAN suggested that these should not be large, but that they should rather be fixed as low as possible, in order to secure a large number of members, leaving the question of donations open as a privilege for those who were generously disposed to aid the Society in that mode of honouring themselves. The Committee of the Horticultural Club, it was here mentioned, would afford room for the Rose Society to transact their business, an intimation which was much appreciated.

Mr. GEORGE PAUL, speaking on the question of subscriptions, thought that an important object to be borne in mind was to gain the affiliation of all local societies and Rose clubs, and to make provision for the embodiment of such clubs on the payment of a subscription to be determined on.

Mr. CAMM thought that nurserymen should pay a great deal more than amateurs; for instance, if he and some of his friends (the small amateurs) were to pay a guinea, his other friends (the great nurserymen) should pay five guineas. The nurserymen would be the principal gainers if the Society became prosperous, and the greatest losers if it collapsed.

The CHAIRMAN observed that it was true that the nurserymen might suffer in pocket if the Society were to fail, but it was equally certain that the amateurs would suffer in mind. To prevent suffering in any form,

Mr. CURTIS, Chatteris, proposed an annual subscription of 10s. as being a reasonable sum for anyone to pay, and he thought that by fixing it thus moderate the large number who would become members would produce a sufficient income for the purposes of the Society. This was seconded by Mr. Cranston.

Mr. BAKER considered a 10s. subscription far too small, and especially for the first year.

Mr. CAMM was of the same opinion, and reminded the meeting that in the case of local societies, such as Exeter and Hereford, the annual subscription was a guinea a-year.

The CHAIRMAN thought they must remember that there were very many earnest and able cultivators of the Rose who would feel it a privilege to become members of the Society, yet who would be unable to do so if the subscription was large. He would not willingly shut out any true rosarian, however humble he might be.

Mr. CANT, as a nurseryman, then proposed that all of his craft should pay five guineas each as a start, and as showing a way of being generous to small growers; but

Mr. DOMBRAIN thought that to agree on a resolution of that kind would be too binding on those who were absent, and he much preferred a simple contribution of 10s., and hoped for donations being offered of various amounts which would be sufficient to give a substantial start to the Society.

Mr. BULMER found in his experience in soliciting support for the Society with which he was connected that he obtained much more money by applying for sums of 10s. than he did by asking for guineas. His policy, therefore, had been to base his expectations on a large number of small sums rather than on a few gifts of greater separate amounts. After this discussion Mr. Curtis's proposition was put in the form of a resolution, and was carried with scarcely a dissenting voice.

The CHAIRMAN proposed that a paper should be passed round for names of subscribers, each gentleman to have the privilege of adding to his name whatever sum he chose to offer as a donation. (During the entering of names the Hon. and Rev. J. T. Boscawen mentioned his gift of two ten-guinea silver cups, to be offered for Tea Roses at Bath; and Mr. Cator also spoke of the determination of the west to make the Bath Show successful.) On the list being returned to the Chairman he made the gratifying announcement that the donations offered amounted to nearly £80, a result which was received with much cheering.

Mr. BULMER now had the pleasure of announcing that Mr. Horace Mayor, Winchmore Hill, had consented to act as joint Secretary with Mr. Dombrain; on which the Chairman observed that all who had had a taste of being secretary would be heartily satisfied that they themselves were not appointed, and that these gentlemen were not only willing but competent for the duties of the office.

Mr. CANT remarked that all knew Mr. Dombrain and admitted his qualifications; but Mr. Mayor, he felt, was a stranger to many, and he thought the meeting would like to hear whether he was a practical Rose grower as well as a willing worker on behalf of the Society. To which Mr. Dombrain replied that Mr. Mayor was a really earnest and able rosarian, and he should feel him on that and other grounds as being a valuable coadjutor. Mr. Mayor resided in the same locality as himself, and on that account also his appointment would be convenient. The appointment of Mr. Dombrain and Mr. Mayor as joint Secretaries was then agreed upon with unanimity.

The CHAIRMAN remarked that the next question requiring to be settled was the election of a Committee, and he was inclined to suggest that the whole of the gentlemen present might well be enrolled as a Committee of the National Rose Society. The number might be large, but it would at the least appear invidious to make exceptions when all alike were earnest and able to assist in the management of the Society. To this suggestion there were sundry replies of "too large," whereupon

Dr. HOGG thought it well to remember that if the numbers there assembled were great they not only represented a National Society, but that the members were necessarily scattered over a wide area, and without a large committee it would be difficult at times to get a strong body together in London for the transaction of business. General assent was given to this view of the question, and

Mr. CAMM created no small hilarity on remarking that he hoped they would all be appointed, because that would afford him an excuse for coming to London. He should often like to be there, but had a difficulty in finding a plea on which his presence was required, but circumstances were now taking a favourable turn.

On the proposition of Mr. Boscawen, seconded by Mr. Curtis, it was resolved that the whole of the members present should form the Committee of the Society.

A discussion next ensued on the nature of the prizes to be offered by the Society, but without, however, arriving at any definite conclusion beyond that it was a matter which the Committee would be better able to decide upon when more experience had been gained and a further accretion of members had been enrolled.

The question of two-days shows was then introduced, and many spoke in no uncertain sound against their encouragement and continuance.

The CHAIRMAN thought they were not likely to be adopted, but was not sure that it would be worth while passing a resolution on the matter when a strong expression of opinion was likely to answer their purpose. His friend Mr. Pochin, whose opinion was entitled to great weight, was doubtful as to the propriety of denouncing them on account of the limited nature of the Rose season, and the loss which might follow in some cases were they not permitted; he thought the matter would find its own level. Mr. Gould had already expressed his opinion in the *Journal of Horticulture* against the continuance of two-days shows, and still adhered to the opinions therein expressed; and Mr. Ellison had stated in a letter that to visit a Rose show on its second day was about as melancholy a task as visiting the corpse of a departed friend. After a considerable interchange of opinion,

Mr. CAMM proposed that the meeting do pledge itself against two-days shows, as being annoying and expensive to exhibitors and insulting to the Rose.

Mr. CANT agreed with much that had been said by Mr. Camm, but could hardly pledge himself for fear of causing loss to others. He would discourage, but not formally refuse.

Mr. DOMBRAIN thought that as the Crystal Palace was only in question it would be sufficient for the managers to be made acquainted with the tone of the present meeting. Others, however, were unwilling to thus leave the matter, and the following resolution was put to the meeting and carried, "That this meeting pledges itself not to countenance a two-days show."

The important matter of judging was then brought forward by the Chairman, who said the National Rose Society should not only have the best judges, but a sufficient number of them to judge not only well but quickly. He rather thought that a good plan for choosing judges would be for each amateur to send in the names of six nurserymen, and each nurseryman to send in the names of six amateurs, and from these the judges be selected according to the number of votes given.

Mr. BAKER remarked in this question a wide field of discussion was opened. He detailed what might be termed the individual "fancies" of some judges carrying at times undue weight in the decisions, and thought it very desirable that some definite standard should be fixed, so that an acknowledged rule of procedure could be followed in the adjudications.

Mr. CANT considered at almost every great show the judges had more classes apportioned them than they could properly manage, and strongly urged the desirability of having more judges.

Mr. DOMBRAIN cordially endorsed Mr. Cant's remarks. He (Mr. Dombain) had often protested against the amount of work which judges had to do in a great show. No work was more exhausting than working hard and long in judging Roses, and, unfortunately, the harder they worked—the more classes they had to judge—the more likely they would be to err in some of their decisions.

Dr. HOGG thought that the selection of judges should be made at each annual general meeting of the Society, when a good attendance might be expected, and not to depend on a small meeting for determining a matter so important.

The CHAIRMAN before bringing the meeting to a close thought it would be well to throw out an idea for after-consideration, as to how far they could arrange a show so as to give encouragement for the growing and arranging Roses, say in the form of a rosery, and

Mr. CRANSTON hoped that bedding Roses and Roses for general garden decoration would not be lost sight of.

A hearty vote of thanks to the Rev. Chairman for his ability in presiding brought to a close the enjoyable, business-like, and well-conducted conference.

### MANAGEMENT OF FRUIT TREES.

I WAS more than pleased with Mr. Taylor's communication on foliage and its relation to the colour and flavour of fruits on page 439. Although we may be able in some small measure to appreciate the long and learned papers of illustrious men, yet who of us have the time even to do so? I have often been amazed when I have been through some of these scientific papers to think what they must have cost the writers—what patience, apart from the toil, such investigations must have occasioned. All I can say is that we are under a great debt of obligation to such men, yet we must not undervalue such practical papers as we often read in the Journal and other kindred publications. What a contrast is our means of acquiring knowledge to the gardeners of fifty years ago! I was forcibly reminded when reading Mr. Taylor's article of my own experience when I practised tree-lifting. The leaves as to size and texture were quite a contrast to leaves of trees under ordinary cultivation. The Pears especially were mostly of the substance of the common Laurel and so glossy as to be like a polished mirror, and of course the fruit was all that could be wished as to size, colour, and texture, so that I was often told by customers, "We cannot get such in London," or "We never saw such in Covent Garden." Apples, too, were fine, as also Cherries and Plums.

I noted too the force of the remark I read only a few days ago—"That if you do not supply proper food for the roots they go along way in quest of it." This I know to be true. I well remember when quite a boy what interest I took in planting stocks to work, and in a sort of freak I planted one stock in nearly all leaf soil, just to see what the result would be. I expected to have a very strong growth, but instead of this there was not a branch over a few inches in length, but such leaves as I had never before seen; so when the autumn came I was very anxious to see what the roots were like, and I do not even now forget how surprised I was—not a root, strictly speaking, but such a mass of fibres so closely set that there did not appear a space between them, and not one gone beyond the new soil. This was what in a great measure took place in tree-lifting. The new soil produced a beautiful lot of fibres,

and the growth was not robust, only a very few inches long, but often six to ten large leaves to an inch, and equally fine buds and flowers following far beyond ordinary flowers.

Now, it is my impression (I may of course be wrong) that such flowers and such growth had a greater power to resist change in temperature; but be that as it may, the best foliage produced the best fruit. This is quite in accordance with Mr. Taylor's experience—best-looking best in flavour—indeed best in every way.

In my experience there is great difficulty in maintaining trees in perfect health without root-lifting—I do not say root-pruning merely, for I do not think this would be sufficient. I will not now go into the comparison between non-pruning and pruning, root-lifting and non-lifting, but will leave this for some future time.—GEORGE LEE, *Clevedon*.

### ROYAL HORTICULTURAL SOCIETY.

ALLOW me to answer one or two questions. Why do we canvass the country for one-guinea and patron four-guinea Fellows instead of trying for Fellows subscribing two guineas?

First, because it has now been shown that a very great many people interested in gardening will subscribe a guinea on general principles to what they believe will be a really useful Society, though they live at such distances from London that they can expect little direct personal good from it?

Secondly, because it is most important that the Society should include as many as possible of the foremost horticulturists of the country of all ranks in full fellowship; and not a few of them, of good position and with considerable influence, have but few guineas to spare and many calls on them.

Thirdly, because the broader the basis the Society rests on the better, the difficulty of collecting subscriptions being not very serious; witness the National Rifle Association and Royal Agricultural Society.

Fourthly, because there are a considerable number of enthusiastic horticulturists with ample means who are willing to lend a helping hand to the Society, especially under its difficulties of transformation, by subscribing £4 4s., for which they will receive a ticket admitting self and friend, and have the right to a second ticket admitting their head gardener to all the Society's shows.

The interest in the guinea fellowships keeps widening. The last post brought in adhesions and names from Durham, Cornwall, Yorkshire, Pembrokeshire, and two from Warwickshire.—GEORGE F. WILSON.

### MANAGEMENT OF HYACINTHS.

ABOUT six or eight weeks after the bulbs have been potted and plunged they will be furnished with roots, and commence making growth. As it is not desirable to have the foliage drawn up weakly, they should be removed from the bed as soon as they grow freely and be placed in a cold frame, excluding frost, and keeping them darkened for a few days. From this frame they may be drafted into the forcing house as required.

In forcing Hyacinths good results may be obtained by placing them in mild bottom heat, and keeping them as near the glass as possible. They should have liberal supplies of water, and liquid manure occasionally, when the pots are well filled with roots. When sufficiently advanced they may be placed on a shelf where they can have free circulation of air, so as to develop the foliage, for long thin leaves are most objectionable; they should be short and sturdy, this being nearly of as much importance as good flower spikes, and can only be obtained by placing the plants near the glass. As soon as the spikes require support they should have stakes of wood or wire put to them, and it must be done with care to avoid injuring the bells. After flowering place the pots in a frame or out of doors until the foliage decays, when the bulbs may be taken up and stored in a dry place, and they will do for planting in the borders in the autumn.

Hyacinths, which are easily grown in glasses, require attention occasionally. The bulbs should just or not quite touch the water. It is not always requisite to change the water, which may be kept pure by placing a piece of charcoal in each glass. As the water lowers through feeding of the roots and evaporation, fresh may be added, but it must be of the same temperature as that in which the plants are growing. The glasses should remain in a cool dark place until they are filled with roots, when they should be removed by degrees to the

light and air, for the more light and air the plants have, the shorter will be the leaves and spikes and brighter the colour of the flowers.

Hyacinths planted in beds will require no more attention than protecting the beds during very severe weather. When in bloom care should be taken to have the spikes supported with stakes, or in rough weather the stems will be broken or the flowers disfigured. It is a beautiful sight in spring to look upon a group of beds well filled with Hyacinths of various colours. Their beauty may be prolonged by placing an awning over them to protect them from the sun and rain. After flowering and the leaves have decayed the bulbs may be lifted and dried, and they will come in useful again for the borders another season by affording small spikes of flowers to cut from.

—ALFRED ALDERMAN.

### THE ROSE CONFERENCE.

A MISERABLY dull winter's day, the rain pouring down; a long, low, dark room, through which the feeble light only penetrated a few feet; a long table all down the room, at which are seated rosarians from every part of England. Such was the scene of last Thursday at the Horticultural Club.

What means it? What has brought Hercules from Exeter, Reynolds Hole from Newark, Cant from Colchester, Paul from Cheshunt, and Cranston and Bulmer from Hereford—at this time of the year too? Not the cattle show! No, don't say that. Fond as we may be of beef in the shape of a well-cooked sirloin, we don't come up two hundred miles more or less to look at fat stock. Not a dinner, dear as it is to Englishmen—and though I believe a dinner was the appropriate end of the meeting—but simply love for the Rose, and an eager desire that her claims as the queen of flowers should still be recognised by, if not the public, at least by all true rosarians, at an exhibition in London during the coming year.

But someone will ask, Are there not already good Rose shows in London? Are not the classic shades of Brompton Boilers consecrated once a-year by the presence of the Rose? Is not the huge glass house at Westminster, called an Aquarium, where there were no fish, and a Winter Garden now because there are no flowers—is not this building devoted once a-year at least to the worship of Rosa? Is not, too, a small edifice in the north of London, called after the fair daughter of the northern sea, beautified for one day at least in the twelvemonth by the choicest gifts of Nature? All these are delights of the past, not to be enjoyed again. They may live, perhaps in the memory, but that is all. Alexandra Palace, Aquarium, and Horticultural Gardens are extinct so far as Rose shows are concerned; and if we want to show our queen of flowers to our town relatives, and to give to the general public their accustomed treat of a feast of sweet things, we must take time by the forelock, conceive, and carry out some good scheme.

This was felt by all rosarians, and no doubt equally so; but it chanced that at the hospitable board of Mr. Cranston of Hereford, on the evening of the West of England Rose Show, a few of the more illustrious members of Rosa's court were gathered together, and they hit upon the scheme of reviving the old National Rose Society. A certain man who is not unknown to your readers, seeing that nearly every number of "our Journal" has a letter signed "D., Deal," determined to press the matter, though, judging by his name, he was but a poor wooden support, yet in deed a man of iron nerve and action, and he sent round circulars to all the leading rosarians, nurserymen, and amateurs, calling a meeting for the 7th of December, and asking them to attend for the purpose of forming a National Rose Society.

And well the rosarians responded—from north and south, east and west we came. The wise men from the east came, as is fitting at this season, in great force, and, strange to say, their number was three!—Messrs. Cant of Colchester, George Paul of Cheshunt, and W. Paul of Waltham. From Devon there came Hercules, and from Oxford we had the Seedling Briar; from Surrey, Captain Christy and Mr. Noble; from Hereford Messrs. Bulmer and Cranston; from Nottingham the Chairman (Rev. Reynolds Hole); and from Kent Malle. Marguerite Dombrain—I beg pardon, I mean her brother, Honeywood Dombrain; but I am so accustomed to writing the former name on labels that I keep thinking there is only one Dombrain who has anything to do with Roses. Most of the editors of the horticultural journals were also present. Never at any great London exhibition have I seen such a gathering; and a glorious thing it was to see how men from all parts of England

put themselves to inconvenience rather than refuse to rally at the call of the Rose, our queen.

The meeting was, in the opinion of old rosarians, the most successful ever held. A National Rose Society was formed, £80 was subscribed in the room, the day and place for the first show was fixed, secretaries and committee were chosen, and all went merry as a marriage bell. If the National Rose Society does not prove successful it will not be because the preliminary meeting was not well supported, for everything that is required to make a meeting a success was present on Thursday—unanimity of feeling, great enthusiasm, and what is more (and this is a crucial point) a general liberal unbuttoning of the pockets.—WYLD SAVAGE.

### NEW BOOK.

*The Effects of Cross and Self-fertilisation in the Vegetable Kingdom.* By CHARLES DARWIN, M.A., F.R.S. London: J. Murray.

THIS volume is well deserving perusal by all gardeners who desire to understand thoroughly the scientific foundations of their art. We can only make one extract, but it epitomises the fuller details of the work.

"The first and most important of the conclusions which may be drawn from the observations given in this volume is that cross-fertilisation is generally beneficial, and self-fertilisation injurious. This is shown by the difference in height, weight, constitutional vigour, and fertility of the offspring from crossed and self-fertilised flowers, and in the number of seeds produced by the parent plants. With respect to the second of these two propositions—namely, that self-fertilisation is generally injurious, we have abundant evidence. The structure of the flowers in such plants as *Lobelia ramosa*, *Digitalis purpurea*, &c., renders the aid of insects almost indispensable for their fertilisation; and bearing in mind the prepotency of pollen from a distinct individual over that from the same individual, such plants will almost certainly have been crossed during many or all previous generations. So it must be, owing merely to the prepotency of foreign pollen, with Cabbages and various other plants, the varieties of which almost invariably intercross when grown together. The same inference may be drawn still more surely with respect to those plants, such as *Reseda* and *Eschscholtzia*, which are sterile with their own pollen, but fertile with that from any other individual. These several plants must therefore have been crossed during a long series of previous generations, and the artificial crosses in my experiments cannot have increased the vigour of the offspring beyond that of their progenitors. Therefore the difference between the self-fertilised and crossed plants raised by me cannot be attributed to the superiority of the crossed, but to the inferiority of the self-fertilised seedlings, due to the injurious effects of self-fertilisation.

"With respect to the first proposition—namely, that cross-fertilisation is generally beneficial, we likewise have excellent evidence. Plants of *Ipomoea* were intercrossed for nine successive generations; they were then again intercrossed, and at the same time crossed with a plant of a fresh stock—that is, one brought from another garden; and the offspring of this latter cross were to the intercrossed plants in height as 100 to 78, and in fertility as 100 to 61. An analogous experiment with *Eschscholtzia* gave a similar result as far as fertility was concerned. In neither of these cases were any of the plants the product of self-fertilisation. Plants of *Dianthus* were self-fertilised for three generations, and this no doubt was injurious; but when these plants were fertilised by a fresh stock and by intercrossed plants of the same stock, there was a great difference in fertility between the two sets of seedlings, and some difference in their height. *Petunias* offer a nearly parallel case. With various other plants, the wonderful effects of a cross with a fresh stock may be seen in Table C. Several accounts have also been published of the extraordinary growth of seedlings from a cross between two varieties of the same species, some of which are known never to fertilise themselves; so that here neither self-fertilisation nor relationship even in a remote degree can have come into play. We may therefore conclude that the above two propositions are true—that cross-fertilisation is generally beneficial, and self-fertilisation injurious to the offspring."

### THE NATIONAL AURICULA SHOW.

I EXCEEDINGLY regret to find that an observation I made with regard to this Show has given cause for observation. The fact is that I misunderstood Mr. Horner's letter to the Secretary, and thought that the National was to be held in the north, and a national one in the south. I am very glad indeed to find that I was mistaken. When the last National Show was held at the Regent's Park I had a good deal to say to it, and no one can more thoroughly rejoice in the thought that the

great tournament of my favourite flower is to be held in London, and I wish it every success.—D., Deal.

### AN ELECTION OF APPLES.

THIS is a very good notion, and I hope will be caught up by orchardists who grow fruit for sale, and by amateurs with whom the Apple is a favourite, and who, perhaps, grow the trees principally as espaliers or pyramids. As this is such an age for exhibitions I would say that classes best suited for this purpose for all seasons be added to Mr. Robson's otherwise admirable arrangement. The two terms, "beauty and utility," seem to point out the requisites for exhibiting, save perhaps in some very marvellous-sized fruit, like the huge Pears at a London dessert which are only to look at. I can scarcely understand that any really bad-tasting and useless Apples should, even with good looks, be cultivated. The Apple is the poor man's fruit as well as the fruit of the middle classes, and its importance as an addition to food can scarcely be over-estimated.

"A MIDLAND COUNTIES FRUIT-GROWER," whom I thank for his valuable article of November 16th, somewhat mistook my meaning as to midseason Apples. I want to know the best among them as for other seasons, but usually there are so many in gardens that people would hesitate to cut them down to make room for others. While the very early and the very late being so few, these could be added to existing stocks of trees.

I must add in conclusion that it gives me unfeigned pleasure to see papers again with the good old signature of J. Robson at their end. Right glad am I that the instructive-writing veteran of so many past years is again well enough to give us the fruits of his great experience; and Mr. Robson is and always has been such a thoroughly sensible writer, that he may long be spared to us is the sincere wish of—WILTSHIRE RECTOR.

### THE HORTICULTURAL CLUB.

THE annual Meeting of the Club was held on Wednesday last at the Club house, 4, Adelphi Terrace, and it is in a condition so flourishing that it was determined to invest a considerable sum in the three per cents. Several new members were proposed, and the arrangements for the comfort of the members were considered excellent. After the meeting the members dined together under the presidency of the Hon. and Rev. J. T. Boscawen. The following is the list of the Committee for the ensuing year:—Herbert Adams, Enfield Chase; J. T. Bartlett, Peveril Park, Aylesbury; Henry Bennett, M.D., The Ferns, Weybridge; Wm. Bull, King's Road, Chelsea, S.W.; Hon. and Rev. J. Townshend Boscawen, Lamorran, Truro; Albert Christy, Buckhurst Lodge, Westerham; Philip Crowley, Waddon House, Chroydon; James Cutbush, Highgate, N.; George Deal, 11, Carlyle Square, Chelsea, S.W.; John Denny, M.D., Stoke Newington, N.; Robert Hogg, LL.D., 99, St. George's Road, Pimlico, S.W.; Rev. S. Reynolds Hole, Cauntton Manor, Newark; Andrew Henderson, Pine Apple Place, N.W.; John Lee, Royal Vineyard, Hammersmith, W.; W. A. Lindsay, 16, Cromwell Road; Horace K. Mayor, Winchmore Hill, N.; Thomas Moore, Botanic Gardens, Chelsea, S.W.; Maxwell T. Masters, M.D., Wellington Street, Strand, W.C.; Charles Noble, Bageshot; Charles Turner, Slough; Harry J. Veitch, King's Road, Chelsea, S.W.; George F. Wilson, Heatherbank, Weybridge; B. S. Williams, Holloway, N.; Maurice Young, Godalming. Secretary, Rev. H. Honeywood Dombrain, Westwell Vicarage, Ashford, Kent.

### POTATO CULTURE.

I QUITE agree with "A YOUNG AMATEUR" (see page 463) on the culture of this useful vegetable. Last year I planted some Potatoes in November, some in January, and the main crop the first week in March; others I planted as late as the last week in April. The result was, those that were planted in March appeared first above ground, and were cut off by frost but soon recovered, and by the middle of September the tubers were quite ripe, yielding on an average two bushels and a half to the perch. Those which were planted in April grew at an extraordinary rate for a short time, and then drooped, being almost burnt up by the excessive heat. At the end of the summer when they ought to have been ripe they were making the second growth. On lifting them the first crop was spoilt, the second or sub-tubers being totally unfit for use, and the whole crop went to

ruin. November planting is too early on our soil on account of snails eating the sets, but on sandy soil I believe this to be the best time for planting, as the growth becomes well established before the heat of the summer sets in.

I intend next season to have my main crop in by the middle of January if the weather permits. I think it the best time for planting in this district. By planting thus early better tubers are not only produced, but they are more likely to keep after they are grown. I also think we should go back to seed more than we do. I believe if this plan was followed up we should not be troubled so much with disease as we have been of late years.—E. BROOK, Westbere, Canterbury.

### NOVELTIES IN THE ROYAL GARDENS, KEW.

PARROTIA PERSICA is one of the most ornamental and interesting of the plants trained on the walls. It is one of the rarest trees in cultivation, and the leaves in autumn assume the most brilliant tints of orange, yellow, and scarlet. This year, however, the leaves have varied from the rule, and are nearly all of the purest yellow. They are still attached to the tree, and likely to be so for some time. It is only when against a wall that the tree retains its beauty for so long, and though quite hardy it is worth having in this position on that account. In form and venation the leaves are something like those of the Beech, but much larger, being 3 or 4 inches long. Good plants are soon obtained by layering the lower branches, and this has hitherto been the method of propagation. Cuttings placed in heat a few weeks ago are likely to succeed. It belongs to the Hamamelidæ, and there is only one other species, P. Jacquemontiana, a native of the Kashmir Himalaya. The wood is very hard and durable, and in Persia it is known as the "Iron Tree." This species was figured in the "Botanical Magazine" of 1870.

In the Succulent house *Senecio macroglossus*, a very handsome new climber, is coming into bloom. All the year round its glossy Ivy-like leaves are highly ornamental, and during winter the golden-yellow flower heads, nearly 3 inches in diameter, are an additional attraction. It is one of the largest-flowered of a genus numbering nearly one thousand species. No plants are more suitable for room cultivation than succulents, and as this is the best of the extremely few climbers of that class it should find a special sphere of usefulness. It is so remarkably like Ivy as to have been mistaken for it. In the animal kingdom, as a rule, the object of mimicry is easily seen, as for instance when insects resemble leaves, or when butterflies that would otherwise be the prey of birds are so like those of objectionable flavour as to be safe from destruction; but among plants the mimicry, unless it be accidental, is not so easily accounted for. In the same house *Agave Noackii* is in flower. It has a distinct stem and branches at the time of flowering, so as to be quite unlike the most familiar of the genus. This plant has rather a slender main stem, which divides into two others at about a foot from the ground, and these, about 1½ foot long, support heavy Aloe-like heads, which are again branching, so that by-and-by a sort of shrub will be formed.

*Drimiopsis Kirkii* is a handsome evergreen bulb, introduced from Zanzibar by the Royal Gardens three or four years ago, and was until then quite unknown. It is cultivated in the stove, where it forms an attraction to every lover of plants from its *Lachenalia*-like leaves with dark green spots. Some bulbs, as *Lachenalia*, are said to produce bulbils on the leaves where severed from the plant; but certainly none so freely as this: every piece thrown down produces several. The flowers are pale blue, small, and inconspicuous. Near this is the graceful *Aralia Veitchii* var. *gracillima*, the leaflets of which are surprisingly narrow, having at the same time the wavy margin of the original. This is an extremely elegant plant, and so also is *A. elegantissima*, which is very distinct from its saw-toothed margins. The *Aralias* are a most ornamental class, having great variety of appearance, and several show in a striking manner the great differences that often may be found between young and old plants of the same kind. Some, indeed, might have different parts of the same plant made into distinct species. *A. leptophylla* is a case in point; young specimens may have the leaflets no more than the fourth of an inch wide, and of very tall plants they may be quite 4 inches, changing in colour from nearly black to green.

Among the Orchids *Liparis pendula* first takes our attention, not on account of colour, but from the numerous and graceful spikes of small green flowers, reminding one forcibly of *Den-*

*drocchilum filiforme*. It is very easily cultivated and affords a pleasing variety. *Cirrhopetalum Medusæ* is very attractive from its curious white tassels formed by the pendulous sepals of about 4 inches in length. *Isochilus linearis* is a peculiar little Orchid, with diminutive bamboo-like stems and leaves, bearing at the extremities rosy-lilac flowers almost like those of a Heath. The favourite genus *Masdevallia* is scarcely ever out of flower, or without the curious and beautiful in bloom at the same time. *M. Daviesi* is just now the newest, and is remarkable for its fine yellow colour. It was named after Messrs. Veitch's collector, who found it near Cuzco in Peru. Others in flower are *M. Veitchii*, *M. ochthodes*, and *M. gibberosa*; the two latter are peculiar in structure but not ornamental.

The *Odontoglossums* are *O. bictoniense*; *O. constrictum*, a light form of *O. nebulosum*; and *O. Roezli*, which beautiful species is sometimes nearly white, but is scarcely then so fine from want of purity. For *Lycaste Skinneri* when introduced was predicted the future of the Tulip. *L. costata*, though of less merit, is worth growing; it has creamy white flowers of large size. Just above this is a basket of *Sophronis grandiflora*, and others of *Restrepia antennifera*. Among the *Oncidiums* are *O. Krameri*, *O. Papilio*, *O. cæsius*, and *O. ornithorhynchum*. *Cypripedium Sedeni* is now the finest of the genus, and is one of the most valuable Orchids in flower. With it also are *C. biflorum*, a quantity of *C. insigne* and *C. Roezlii*, which may be considered a finely coloured variety of *C. longifolium*.

### WINDOW GARDENING.

In planting a window garden seek ornamental foliage for it rather than very many flowering plants. True, every blossom is precious in winter; hence the more Carnations, Primroses, and other flowers one can have the better. Still, the choice between a handsome plant having brilliant leafage, and an ugly-looking one having poor leaves but pretty blossoms, must be decidedly in favour of the former. A *Begonia Rex* is better than a *Petunia*. A *Dracæna terminalis*, a small Tree Fern, or a tricoloured *Geranium*, looks much finer in the window than a Rose bush, a *Daphne* or a Cactus, especially when these cannot be coaxed into blooming. It would be unfortunate not to have a few flowers enough for the crowning grace of the collection, but for the continuous quiet beauty of a window garden let broad-leaved ornamental foliage be the main reliance. Happily some plants have beautiful leaves and flowers also; thus far they are well adapted for parlour use. We can fill our window box, if we choose, with plants of finest, rarest foliage, and then add brilliant flowers, such as *Duc Van Thol* and other early Tulips, Hyacinths, and Crocuses. By cultivating these, each bulb in a separate pot, bringing them into bloom, and disposing them around among the plants, concealing the pot as far as possible, we shall secure all that is desirable in the way of beauty, colour or fragrance.

An *Amaryllis* that blooms for a month in midwinter may give much satisfaction. The flaming scarlet of its blossoms may be toned down with silver-leaved *Geranium* on one side, and *Crystal Palace Gem* on the other, while the delicate-coloured foliage of these plants will be heightened in effect by the contrast. Plants suitable for a single pot, bracket, or vase are found in great variety; all flower-growers know what they are—*Callas*, *Fuchsias*, *Caladiums*, &c. Well cared for, almost any plant looks well; neglected, the best of them becomes a nuisance. Even the *Sedum spectabile* makes a fine window plant by putting it in the cellar in autumn, repotting and bringing into the sun in January. It soon grows up from the stools, branches out, and spreads itself, while every leaf, of a rich cream colour, edged with green and slightly curled, is as handsome as a shell. Gardening is very much like house-keeping in this, more or less of the individual will be expressed therein. If one has good perceptions of colour, contrast, and harmony, and is deeply imbued with a love of her subject, she needs but little instruction from art critics to arrange her plants gracefully and her home with refinement.—(*New York Tribune*.)

### OUR BORDER FLOWERS—GESNERWORTS.

*RAMONIA PYRENAICA*, or, as we used to call it, *Verbasum Myconi*, is one of those gems that need only to be seen to be appreciated. Strictly speaking it scarcely comes under our heading, for its proper place is on the rockery, or it is better still when grown in pots. It can be used for all purposes that

plants are adapted for, and is a telling plant in a collection of alpine for exhibition. We are indebted to the Pyrenees for this much-neglected and choice occupant of moist shady nooks. There is little difficulty in cultivating this plant. It may be increased by seed sown as soon as ripe in well-drained pots placed in a cold pit or frame and carefully watered, admitting fresh air on all favourable occasions. It is good practice to afford the plants a little protection in severe weather; they are increased by division also. They require thorough drainage under all circumstances. A compost of sandy loam and peat in equal quantities, with a sprinkling of charcoal dust, will meet their requirements. They cannot endure full sunshine, therefore partial shade should at all times be afforded them. When well cultivated these plants cannot fail to be admired.—*VERITAS*.

### SPECIMEN POMPON CHRYSANTHEMUMS.

In offering a few remarks on the culture of these plants I wish it to be understood that the production of really good specimens depends more on the care and enthusiasm of the cultivator than on any instructions he may receive. If this be borne in mind there may be less complaint that, after having received directions, so little has actually been learnt from them.

To produce good specimens, choose strong cuttings about the end of November, and insert them in sandy soil; water, and place the cutting-pots in a cold frame, and keep rather close for a month or so. They must be sprinkled occasionally and shaded from sunshine till rooted, after which give plenty of air at all times except when frosty. By no means endeavour to excite growth by artificial heat, for by inducing growth in the dark days premature flowering often happens with some of the early sorts. About the end of February the rooted plants may be potted-off into 3-inch pots, using a compost of loam and leaf soil, with enough silver sand to keep it porous. Replace in a cold frame, tilting the lights, or removing them altogether when the weather is mild. When the plants have attained the height of 6 inches stop them and repot into 6-inch pots, using a little more loam and less sand than before. When the side shoots are about 4 inches in length the shape of the plant must be determined on. If for a pyramid (as in the annexed illustration) one shoot must be allowed to grow erect and the others be tied out; but great care is necessary in handling, for the shoots of some varieties are apt to split and break off at the joint. If the plants are wanted for dwarf specimens all the shoots must be trained out laterally.

About the end of May shift the plants into their flowering pots, 3-inch pots being suitable. The compost must not be sifted, and should consist of three parts good holding loam and one part of well-decayed manure and leaf soil. I have also found a 6-inch potful of soot to every bushel of soil very beneficial. The drainage must also be efficient, not, however, placing too many crocks in the bottom of the pot, and using turfy loam to prevent the finer soil getting down amongst them. The plants should be potted rather firmly, leaving about half an inch of space on the surface of the soil for watering. When this is done, if the weather is not too cold, place the plants on a south border outdoors in the full sun on pieces of slate, or, which are better, inverted flower pots sunk into the ground, the superfluous water passing away more readily than from slate bases. The plants should be placed quite a yard apart from each other; 4 feet would be better, as that allows plenty of room to walk between and attend to them, and the pots should be earthed-up to prevent evaporation. A zinc-wire hoop from 18 inches to 2 feet in diameter should now be placed at the base of each plant, supporting the wire by two sticks crossing each other, and fastened to the pot. To this wire the shoots can be drawn down readily; and if the plants are intended for pyramids a stick 3 feet in height may be placed upright near the centre of the pot, for by the end of October many kinds will have reached that height and be filled out proportionately, one stick and a hoop being quite sufficient for pyramids, and a hoop alone for dwarf-trained plants, a quantity of sticks not being at all necessary for good training.

From this time till the plants have done flowering they should never want for water. No fixed rule can be laid down as to how often they should be watered, for much depends on the state of the weather; but when water is required give abundance, filling the pot up twice, for if the plants are once allowed to flag rapid loss of foliage is a sure consequence. From the end of July to the end of October clear weak liquid

manure water may be given three times a-week, for the Chrysanthemum is a voracious feeder. I have used the word "clear," and it is important, for if the manure water is used in a thick state the sediment forms a coating over the surface of the soil, excluding air and rendering the plant less vigorous. Sprinkling overhead on the afternoon of fine days just before the sun goes down induces rapid growth and keeps the plants healthy. From June onwards Chrysanthemums grow quickly, and if good bushes are required the plants must be looked over once a-week, and any shoots that are 4 or 5 inches long must be stopped, always pinching out the extreme point; and as they grow they must be trained, care being taken not to have the ties too tight, and carefully remove all suckers that arise from the root, as they rob the head.

A little judgment is necessary in training the plants, for if a pyramid be required a good leading shoot must be selected and stopped before growing too high. The best shoot from this stopping should again take the lead, the side branches being trained out regularly. As regards the time that the plants should be last stopped much depends upon the varieties that are grown, and whether it is required to have them all in perfection at about the same time; for many varieties, such as Bob and some of the Anemone-flowered sorts are much later than others, such as the Cedo Nulli. The end of June I have found to be quite late enough for stopping the late-flowering varieties, but the early sorts may be stopped till the third week in July. They may be stopped later and then bloom, but the quality of the flowers is not so good.

Towards the latter end of September the plants will show flower buds, and when these are large enough to handle all but the best on each shoot must be taken off, for one good bloom for exhibition is better than three or four small flowers. The plants should have their last tying about the second week in October, for if delayed till a week or so before they bloom they never look so well. Distribute the blooms equally all over the plant, which will not be much trouble if the training has been regularly attended to throughout the summer. The pots may now be lifted out of the plunging material, have plenty of room, and be placed in the full sun, for without well-ripened wood good flowers must not be expected; and on no account must the plants be allowed to be dry, using water at all times, if possible, that has been well exposed to the air. The sprinklings overhead may also be discontinued after the end

of September, for with dewy nights and less solar heat too much moisture about the foliage encourages mildew, a good preventive of which is a dusting of sulphur or soot, but the latter I prefer.

The plants should be taken into a well-aired light greenhouse on the approach of frost, and be dewed overhead with a syringe every morning till the flowers show colour, and with a few sunny days and a little fire heat on frosty nights to keep the house comfortable they will be in good condition by the first and second week in November.

The following varieties I have found make very good specimens, but there are many others more or less suitable:—Bob, Mdle. Marthe (two of the best), Astræa, St. Michael, Antonius, St. Thais, White Trevenna, Rose Trevenna; White, Lilac, and Golden Cedo Nulli; Rose Marguerite, Golden Circle, Calliope, Hélène, Madame Montels, Marie Stuart, Mr. Astie, La Sultana, Adonis, Aigle d'Or, Rose d'Amour, Brilliant, and Mrs. Hutt.

Standard Pompons are very ornamental, and may be produced by taking a strong-rooted sucker 6 inches in height of any of the tall-growing kinds. These should be potted in 6-inch pots as soon as the plants have done flowering, placing in a warm greenhouse, tying upright as they grow, and when of the desired height stop them. After they have pushed fresh growth freely pot them into their flowering pots and place outdoors with the others. A hoop may be placed to form the head by driving three stakes in the pot in a triangular manner, and to these fasten each hoop with wire. When the plants are housed the three supports may be cut away, leaving the hoop attached to the head of the plant with only a stout stake in the centre for support.—A. HARDING.

[The engraving is from a photograph of

a plant of Mdle. Marthe exhibited by Mr. Harding at the Brixton Show. The plant was 3½ feet in height and 2½ feet in diameter at the base, and was skilfully trained and cultivated.—EDS.]

## EARLY WRITERS ON ENGLISH GARDENING.

No. 23.

JOHN RAY.

I FOUND the last of John Ray's known collateral relatives an old woman at the "Ship" inn, at the Hythe, Maldon, Essex, and the memory of her celebrated ancestor was retained by her,

for she had his portrait, taken from Derham's biography of him, framed, and hanging on the wall by her side.

It is not generally known that his father, a blacksmith at Black Notley, spelt his name "Wray," and that his celebrated son dropped the W. The name has been derived from the French *vrai*, true, and one branch of the family have the canting motto, *Juste et vrai*, Just and true.

Many years ago I wrote and published the following in your columns:—If a pilgrim loving to visit the places where the good and the great have dwelt and rest from their labours, will convey himself to the good old Essex town of Braintree, and, staff in hand, will turn down by the east end of its stately church—a structure that will live in all legal memories for ever in connection with its 'Church Rate Case,' and will pass on for some two miles along the road that leads to Witham, he will arrive at a little white church, plain and unattractive, with cottages appropriately nestling near it, and among them that of the village blacksmith. His forge, with the exception of the broad brick chimney, wears but a modern and no markedly thriving aspect; but that chimney must have vibrated with the echoes of the hammer's measured blows two centuries since; and who then stood by its side, and submitted the iron to their blows? No other than the father of the most excellent botanist that England numbers among its natives—even the father of the English Linnaeus, John Ray. In the cottage attached to that smithy was this admirable man born on the 29th of November, 1627; by the side of that smithy chimney was his childhood passed. But he was no common boy; and the squire of the parish—a Mr. Wyvill, if we remember correctly—hearing of his rapid progress as a scholar at Braintree school, aided to sustain him at Catherine Hall, Cambridge, and subsequently at Trinity College in the same University, whither he removed, 'because in Catherine Hall they chiefly addicted themselves to disputations, while in Trinity the politer arts and sciences were principally cultivated.' In 1649 he was, at the same time as Isaac Barrow, elected a Fellow of his college; and the learned Dr. Dupont, famous for his skill in Greek, used to say that of all his pupils none were comparable to these two. That he was not deceived in his estimate of Ray is evidenced by the fact that, before he was twenty-seven, in 1655, he had been successively elected Greek lecturer, mathematical lecturer, and humanity reader of his college. He was also tutor to many gentlemen of high standing, but with none did he acquire so close a friendship as with Francis Willughby, and with whom in after years he was intimately associated in scientific researches. Ray was always fond of natural history, but he especially became attached to botany from one of those providences we are so prone to characterise as accidents, which, though apparently evils, are in reality the seed time of a future rich harvest of good. A violent illness—probably the result of intense sedentary study—rendered necessary the remedy of much outdoor exercise; and as Ray was not of that class who can endure mere mechanical exertion without an accompanying object of mental improvement, he devoted his walks to the collection and examination of wild plants—researches which he continued for ten years, and which gave birth, in 1660, to his "Catalogue of Plants produced in the Neighbourhood of Cambridge." In its preface he describes the difficulties he had to overcome in the prosecution of his botanical studies, especially the absence of a guide in the determination of species; yet he surmounted all difficulties, and succeeded in describing alphabetically 626. Many notes, abounding with original observations on plants and insects,

are dispersed throughout the volume, all evincing signs of that excellence and celebrity to which he afterwards attained. At the Restoration of Charles II., 1660, Ray was ordained a clergyman of the Church of England; but he never held any preferment, nor performed regularly parochial duty; and two years afterwards he was obliged to resign even his Fellowship, whereby his entire living was taken from him, because his conscience would not permit him to subscribe the Act of Uniformity. Yet there was no fanaticism, but the purest tolerant spirit within him; and how fitted he was to adorn his profession may be appreciated from that excellent little volume by which he is most popularly known, "The Wisdom of God Manifested in the Works of the Creation."

The following are details of his career: He was chosen minor Fellow of Trinity in 1649; in 1651 was made Greek lecturer of the College; in 1653 mathematical lecturer; and in 1655 humanity reader. He afterwards passed through the offices of the College, and became tutor to many gentlemen of honourable birth and attainments, who gave him due praise and acknowledgments for his watchful care of them.

At the period when Mr. Ray turned his attention to the study of nature, the knowledge of plants was not highly superior to the state in which Turner had found it in the same place more than a century before. In this study Ray could find no master. We are not able to say that a single publication of a scientific nature on the subject of plants had ever appeared at Cambridge, for Maplet's "Green Forest" will scarcely be thought worthy of that appellation. Oxford had, indeed, not only experienced the benefit of private encouragement, but of public munificence, in the establishment of a garden. But at the sister University Mr. Ray stood alone, himself indeed a host! Self-taught as he was, and full of ardour, he so forcibly displayed the utility of botanical knowledge, and its intimate connection with the arts and conveniences of life, independent even of those charms which the views of nature ever afford to contemplative minds, that he soon made it an object of attention, and numbered among his associates in these studies Mr. Nid, a senior Fellow of his own College, Mr. Francis Willughby, and Mr. Peter Courthorpe.

Among the variety of notes in his catalogue of Cambridge plants, Mr. Ray informs us that the people of Norwich had long excelled in the culture and production of fine flowers, and that in those days the florists held their annual feasts, and crowned the best flower with a premium, as at present.

The desire Mr. Ray had to extend his knowledge of English botany had induced him in the autumn of 1658 to take a journey, which he performed alone, through the midland counties of England and the northern part of Wales, in search of plants. This tour held him from August 9th to September 18th. Of this and of two other tours Mr. Ray preserved some short memorandums, in which he has noticed his daily progress, some remarkable facts that occurred, some observations on the antiquities that he met with, and some of the rare plants. Dr. Scott has published these itineraries with his life.

We read with interest in his itineraries the records of his first finding various plants, some in the gardens he visited, and others growing wild. As examples we note *Lupinus luteus odoratus*, Yellow Lupine, which, long before, Gerarde describes as having "floures of an exceeding faire gold yellow colour, sweet of smell. They grow in my garden, and in other men's gardens about London." He also notes as new to him *Vaccinium rubra*, now called *Vaccinium Vitis-idaea*, commonly

Fig. 75.—JOHN RAY.

called the Red Bilberry, Whortleberry, and Cowberry. He visited the garden of Dr. Johnson at Pontefract, and records that he never before saw *Solidago Sarracenica*, *Scrophularia Tradescanti*, and some others. Crossing into Scotland Ray notices in the garden of Mr. Stuart at Stirling "divers exotic plants, more than one would hope to find in so northerly and cold a country." Some Ray had not before seen. One sentence appears to record the first finding in Wales of the Maiden-hair Fern, for at St. David's Head he says he found "the plant I call *Polypodium marinum* growing on many of the rocks by the seaside, which it is likely the herbarists may call *Filix marina* or *Adiantum*." Ramsey Island, he observes, was so called from the Ramsons (*Allium ursinum*) plentifully growing there. The names of the plants not natives of England which he published in his "Travels through the Low Countries" are only alphabetically arranged, with brief descriptions and the places where he observed them. The particulars are in Latin, and a translation of one will show the character of the work. "*Papaver corniculatum* (Horned Poppy) with crimson flower. In Attica, in the neighbourhood of Hymettus." This is from his "*Stirpium orientalium rariorum Catalogus*."

In his subsequent journeys he was commonly accompanied by some friends of a congenial taste; thus, in his second tour in the autumn of 1661 Mr. Willughby and some other gentlemen travelled with Mr. Ray into Scotland through the counties of Durham and Northumberland to Edinburgh, Glasgow, and back through Cumberland and Westmorland. This journey held six weeks, from July 26th to August 30th. In 1662 Mr. Ray, accompanied by Mr. Willughby, took his third and most extensive English tour through the middle counties of England into Cheshire, thence into North Wales, and through the middle Welsh counties into Pembrokeshire, coasting the southern part to Bath and Bristol, thence to the Land's End through Somerset and Devon, returning through Dorsetshire, Wiltshire, and Hampshire. They were absent in this excursion from May 8th to July 18th, and Mr. Ray gathered a plentiful harvest, which afterwards enabled him to enrich his general "Catalogue of English Plants," then in meditation. Nor did he omit to avail himself of every opportunity, particularly at Tenby in Wales, and in Cornwall, of describing such birds and fishes as were less frequent in other parts, preparatory to his intended publications in zoology.

In 1663 he published an appendix to the "Cambridge Catalogue," containing emendations and the addition of forty-two plants; and in 1685 came out another appendix, with the addition of sixty more not noticed before, which were principally communicated by Mr. Dent of Cambridge.

Being now at liberty from the constraints and business of a college life, he was led to accompany Mr. Willughby, Mr. Shippin, and Mr. Nathaniel Bacon, two of them his pupils, to the Continent. Mr. Ray was absent from April 18th, 1663, to March 1665-6, during which time they visited France, Holland, Germany, Switzerland, Italy, and extended their journey to Sicily and to Malta.

On his return from the Continent he spent the summer of 1666 between his friends in Essex and Sussex, and in reading the publications which had appeared in England during the three years of his absence. The winter passed in reviewing and arranging the museum of his friend and pupil, Mr. Willughby, rich in animal and fossil productions, in arranging his own catalogues for his general list of English vegetables, and in framing the tables for Dr. Wilkins's "Real or Universal Character."

In the summer of 1667 Mr. Ray, accompanied by his much-honoured friend Mr. Willughby, made his fourth excursion into the distant counties. They left Middleton Park on June 25th, and took their route to the Land's End through the counties of Worcester, Gloucester, and Somerset, and returned through Hants to London on September 13th.

On November 7th of this year he was chosen Fellow of the Royal Society, and was prevailed on by Bishop Wilkins to translate his "Real Character" into Latin. This he performed, though it was never published, and the manuscript is extant in the library of the Royal Society. The latter end of the year and the beginning of 1668 he spent with gentlemen who had all been his pupils at Trinity: Mr. Burrell and Mr. Courthorpe at Danny, in Sussex; Sir Robert Barnham at Bocton, in Kent; and with Mr. Willughby, in Warwickshire. In the autumn of this year he took his fifth journey alone into Yorkshire and Westmorland, returning in September to Middleton Hall, and spent the winter with Mr. Willughby, then lately married.

About this time Dr. Tonge, Dr. Beal, and some other philosophical gentlemen in England, were busied in experiments relating to the motion of the sap in trees. Among these also in the spring of 1669 Mr. Ray and Mr. Willughby entered upon a set of the like experiments, and induced Mr. (afterwards Dr.) Lister to prosecute the same. These experiments were made on the Birch, the Sycamore or Greater Maple, the Alder, the Ash, the Hazel, Chestnut, Walnut, and Willow, of which the two first were found to be the best adapted to the purpose from their bleeding most freely.

In 1671 Mr. Ray wrote a paper, printed in the "Philosophical Transactions," No. 74, on the subject of spontaneous generation, a point of philosophy which had been much discussed, and to which some among the learned were yet attached. It appears from this paper that he very early rejected this doctrine, and was confirmed in his opinion by the experiments of Redi. In this year he drew up his "Catalogue," and dedicated it to his friend and Mæcenas Mr. Willughby under the following title, "*Catalogus Plantarum Angliæ et insularum adjacentium tum indigenarum tum in agris passim cultas complectens*."

In this year he informs Dr. Lister that he had what he thought a most liberal offer of £100 a-year and all his expenses defrayed to accompany three young gentlemen abroad. But he declined it, although he much wished to have taken a review of the alpine plants. Indisposition had some share in this refusal, and we find that in the next spring, 1671, he suffered much from a jaundice. He was so far recovered, however, before July as to be able to set forth on his sixth journey, in which he took with him Thomas Willisel, an unlettered man, but one whose love for plants, and his zeal and assiduity in collecting them, merits commemoration. They travelled through Derbyshire, Yorkshire, and all the northern counties, as far as to Berwick, and back through the bishopric of Durham.

In the same year died, to the unspeakable loss and grief of Mr. Ray, his most valuable friend Francis Willughby, Esq., on July 3rd, in the thirty-seventh year of his age. The strictest intimacy had subsisted between them from the time of their being fellow collegians, and it was cemented by a congeniality of taste, which not unfrequently forms a stronger bond of union than the ties of blood.

For the use of his pupils (Mr. Willughby's two sons) Mr. Ray drew up in 1672 his "Nomenclator Classicus," induced thereto by observing the multitude of errors in the names of plants and animals in the manuals of daily use.

On November 19th, 1672, he sustained in the death of Bishop Wilkins the loss of another of his best friends, and it is not unreasonable to conjecture that these privations added strength to his motives for domestic retirement, and accelerated at least that connection he made the next year, when he married Margaret, the daughter of Mr. John Oakely of Llannton in Oxfordshire. They were married in the church of Middleton on June 5th, 1673.

In the same year Mr. Ray gave to the public the fruit of his foreign travels under the title of "Observations Topographical, Moral, and Physiological, made in a Journey through part of the Low Countries, Germany, Italy, and France." To the end of these "Observations" is affixed an alphabetical list of the plants mentioned in the body of the book, under the title of "*Catalogus Stirpium in exteris regionibus, a nobis observatarum, quæ vel omnino vel parce admodum in Anglia sponte proveniunt*."

Mr. Ray continued after his marriage to reside at Middleton Hall, where his engagements at this period of his life were such as called forth all the talents of his literary abilities and demanded all his care as a faithful guardian. He was employed in a double duty, that of his trust to the sons of his late estimable friend and of editor to the remains of their father, "On the History of Birds and Fishes." Mr. Ray translated this work into English, and published it with large additions in 1678, with figures engraved at the expense of Mrs. Willughby.

Mr. Ray in the year 1674 was induced to engage, at the request of the Royal Society, with other distant members, to furnish observations on the subjects of natural history, to be read at their meetings; the Society, notwithstanding the extreme diligence of the Secretary and some few others, being at this juncture rather in a languishing state.

On this occasion he wrote several papers, of which some were afterwards printed in the "Philosophical Transactions." Among those which were not published, as we find by his letters, were the following: "On the Acid of Ants;" "On a

Fossil of the Figured Kind, found in Malta, and known by the name of St. Paul's Bastoons Letters, page 120;" "On the Trochites," "On Mushrooms," "On the Darting of Spiders," "On the Seeds of Plants," and "On the Specific Differences of Plants."

On the death of the mother of his friend, the Dowager Lady Willughby, and the removal of his sons from under Mr. Ray's tuition, he retired some time in the year 1676 to Sutton Coldfield, about four miles distant from Middleton Hall, where he remained till Michaelmas 1677. He then made a second removal to Falkborne Hall, near Black Notley, at which last place he built a house, and finally settled June 24th, 1679.

Mr. Willughby's "Iethology" remaining yet unpublished, Mr. Ray in 1684 arranged the materials, which had been left in a very imperfect and undigested state. He wrote the two first books himself, revised, methodised, and enlarged the whole, and sent it to the Royal Society, the members of which contributed to furnish the plates, and by the assistance of Bishop Fell it was printed at Oxford, the Royal Society being at the whole expense. It came out under the following title: "Francisci Willughbei, Armig. de Historia Piscium, Libri quatuor, jussu et sumptu S. Ray. Lond. editi. Totum opus recognovit, coaptavit, supplevit, librum etiam primum et secundum integros adjecit J. Raius." Oxon. 1686.

Preparatory to his great work, which he intended to arrange systematically, he put forth in 1682 his "Methodus Plantarum," enlarged and improved from the synoptical tables which he had printed in Bishop Wilkins's "Real Character" in 1668. It bears the following title: "Methodus Plantarum nova brevitas et perspicuitatis causa synoptice in tabulis exhibita."

Mr. Ray informs us that it was at the persuasion of his friend Mr. Willughby that he began to collect materials with a view to a general history of plants; but that after the loss of his friend in 1672 he relaxed, and on hearing that Dr. Morrison was employed on a similar design, from which considerable expectations were formed, at length gave up his purpose. On the decease of Dr. Morrison in 1683, who left the much greater part of his work unfinished, by the persuasion of his friends, and particularly of Mr. Hutton, to whom it was dedicated, he resumed his design, and prosecuted the work with vigour. The first volume was published in the year 1686 under the following title: "Historia Plantarum Generalis: species hactenus editas aliasque insuper multas noviter inventas et descriptas complectens."

After the first edition of the "Catalogus Plantarum Angliæ" was out of print Mr. Ray had been exhorted by his friend Mr. Ralph Johnson to arrange the second according to system; but not having sufficiently elaborated his method at that time he declined it, and it came out in 1677 in the alphabetical order. A third edition being wanted, however, after the publication of the "History of Plants," he meditated throwing it into the systematic form, and in the meantime put forth, in 1688, "Fasciculus Stirpium Britannicarum, post editum Plantarum Angliæ Catalogum observatarum." Lond. 8°. By this little volume a considerable accession was made to English botany; several very rare mountainous or alpine plants from Wales, some scarce ones from Cornwall, sea plants, new Fungi, Mosses, and Grasses made their first appearance in this little catalogue. The "Synopsis," although finished for the press soon after this "Fasciculus," was not published, owing to the delay of the printer, till 1690, when it appeared under this title, "Synopsis methodica Stirpium Britannicarum."

To this period Mr. Ray had appeared to the public principally as a naturalist, but he now united to this character that of theologist. It is needless to say that he succeeded in this department, perhaps beyond most of those who had before written on the same subject. His first publication of this kind we are told was originally and in its outlines college exercises only, or commonplaces. These he now wrought up and enlarged into a convenient volume, and trusted it to the care of his friend, Dr. Tancred Robinson, who procured five hundred copies to be printed under the following title: "The Wisdom of God Manifested in the Works of the Creation." 8°. 1691.

The favourable acceptance the public gave to the "Demonstration" encouraged Mr. Ray to publish the next year his "Three Physico-theological Discourses concerning the Primitive Chaos and Creation of the World," "The General Deluge, its Causes and Effects," "The Dissolution of the World and Future Conflagration."

In this year Mr. Ray wrote some "Observations on the

Planting of Maize instead of Pease," occasioned by a proposal of Sir Richard Bulkley, in which he says that he had found the greatest yield of Pease to be twenty barrels reaped for one sown; whereas, from one grain of Indian Wheat he had calculated the produce would be upwards of two thousand grains for one. These observations were printed in the "Phil. Trans.," No. 209. In 1693 he published his "Synopsis methodica animalium, quadrupedum, et Serpentinum generis."

In the same year, 1693, Mr. Ray became the editor of a translation of "Dr. Rauwolf's Travels." This physician, who was the next after Belon whom the love of natural history alone led to travel into the east, spent the years 1573-4-5 in traversing Syria, Mesopotamia, Palestine, and Egypt, induced as he tells us by his desire to behold in the native places the plants of the Greek and Arabian physicians.

The "Catalogus Stirpium in exteris Regionibus observatarum" being out of print, Mr. Ray was induced to give a new edition of it, with such large augmentations as to make it a new work. This is his "Stirpium Europæarum extra Britannias nascentium Sylloge." About this time Mr. Ray communicated "The Provincial Catalogues of Plants," printed at the end of each county in the edition of "Cambden's Britannia," published in 1695 by Mr. Gibson. This second edition of the "Synopsis" was printed in 1696. 8°. p. 346. Mr. Ray himself had but a small share in the augmentations that were made to this edition. His advancing years and infirmities prevented him from making excursions. His principal auxiliaries are mentioned in the preface, in which, additional to the names in the former "Synopsis," we meet with those of Mr. Edward Lihwyd, Walter Moyle, Esq., and Mr. William Vernon, Fellow of St. Peter's College, Cambridge. With this edition of the "Synopsis" was published the "Dissertatio de variis Plantarum Methodis brevis," in which Mr. Ray shows that the separation of plants into classes and genera from the fructification alone must be a very gradual and progressive affair.

In 1697 he wrote "Some Observations on the Poisonous Effects of a Root Eaten instead of Parsnips," supposed to have been that of the Hemlock, but of which Mr. Ray had some doubt, alleging that it was more probably the *Cientaria vulgaris* (*Chærophyllum sylvestre*, *Linna.*). See "Phil. Trans.," No. 231. In No. 238 he communicated "Remarks on the Poisonous Effects of the *Enanthe crocata*," too fatally confirmed by later mistakes of the same kind.

In the year 1700 Mr. Ray published "A Persuasive to a Holy Life, from the Happiness which attends it both in this World and in the World to Come." Lond. 8°.

So small, however, was the demand for books in botanical science that the London booksellers were unwilling to risk the printing them, and finally printed at Amsterdam under the care of Dr. Hutton, the botanical professor at Leyden, who supervised the press and procured 1100 copies to be thrown off, appeared under the title of "Methodus Plantarum emendata et aucta: accedit Methodus Graminum, Juncorum, et Cyperorum specialis." 8°. p. 202. 1703. Dr. Hutton gave a further sanction to the system of his friend; he taught it in his lectures to the pupils of that University, and informed Mr. Ray of the good acceptance it met with on the Continent, particularly in Italy. The last of his works published in his lifetime came out in 1704 with the following title: "Historia Plantarum Tomus tertius, qui est Supplementum duorum præcedentium."

Mr. Ray's infirmities and afflictions, painful and grievous as they were, did not prevent him from prosecuting his studies till within about three months before his death, which event took place on January 17th, 1704-5. He died at Black Notley, and was buried, as Dr. Derham says, according to his own desire in the church of that parish; although the rector of the parish offered him a place of interment in the chancel of the church, yet he modestly refused it, choosing rather to be buried in the churchyard with his ancestors, where a monument was erected to him at the charge of some of his friends, with a Latin inscription.

He had four daughters, three of whom survived him. He left a small legacy to the poor of his own parish, and £5 to Trinity College in Cambridge, to purchase books for the library there. All his collections of natural curiosities he bestowed on his friend and neighbour Mr. Samuel Dale, author of the "Pharmacology," to whom they were delivered about a week before his death.

Mr. Ray's posthumous papers were entrusted by his widow to the care of Dr. Derham, who, after publishing the "Historia Insectorum," selected a number of his letters and printed

them in 1718 under the title of "Philosophical Letters between the learned Mr. Ray and several of his Correspondents, natives and foreigners."

### CUCUMBER CULTURE.

YOUR correspondent, "J. P.," has on page 472 named five varieties of Cucumbers which have done well with him, but I wish to add a few more to the list and a few cultural remarks. On the 8th of January I sowed the seeds in a bell-glass, using three parts of leaf soil and one part of turfy loam, and placed the glass on the hot-water pipes. The seed soon germinated, and the third day afterwards I potted the plants into 60-sized pots, using leaf soil and turfy loam in equal parts. As soon as the plants were well established they were planted in pure turfy loam. I do not use manure in the soil, for I have proved that planting in rich soil causes excrescences to form on the roots, which are almost certain death to the plants. I use liquid manure two or three times a-week in a warm state when the plants are growing. I began cutting fruit on the 18th of March, and continued until the 28th of October, when the old plants were removed.

The first variety I wish to mention is Sutton's Duke of Connaught. It is very handsome and level fruit, growing from 20 to 25 inches in length, and of excellent flavour. Hamilton's British Volunteer is remarkably productive; it is very tender and good, and grows from 25 to 30 inches in length. Hamilton's Needle Gun is perfectly smooth and straight, and grows from 20 to 28 inches in length, but is rather shy in fruiting. Hamilton's Goliath is very large; it grows from 25 to 30 inches in length, and for a long variety is remarkably free in fruiting. Blue Gown is an excellent variety; it grows from 20 to 26 inches long, regular in shape, and good in flavour. Daniels' Duke of Edinburgh is a fine variety; it is a free-bearer, and grows from 20 to 26 inches in length, it is quite tender, and of superior flavour. The above I consider good exhibition varieties, as well as being serviceable for table use; but as producing fruit fit for cutting freely for everyday use I can recommend Sutton's Berkshire Champion. It is a good variety for frame cultivation, being very prolific and of superior quality. The fruit grows about 20 inches in length. Kirklees Hall Defiance is suitable for either frame or house cultivation; it is prolific, tender, and grows about 20 inches in length. Improved Market Favourite is a most excellent variety for frame cultivation, being a free-bearer, the fruit growing from 15 to 18 inches in length. Sion House Improved is one of the best for winter work; it is a heavy cropper, the fruit growing about 16 inches in length, straight, and of the first quality. The varieties named have done well with me, and I can recommend them as worthy of general cultivation.—G. S., *Faulkners House Gardens.*

### EFFECTS OF ARCTIC TEMPERATURES.

I WILL premise by saying that as I once upon a time spent four summers and two winters in the "Plover," Captain Moore, in search of the "Terror" and "Erebus," under Sir John Franklin, I consider myself entitled to form an opinion about what I am going to state.

Any newspaper account I have seen merely says that Dr. Kane left some Wheat for experimental purposes, but none of them tell under what conditions it was left. If it was left buried in the ground it would never be exposed to a lower temperature than 28°, however cold the atmosphere might be; and if even it was merely laid on the surface of the ground, it is extremely improbable that it would fare much worse, as the snow would fall and cover it before any very severe frost could reach it. During my stay in the Arctic regions we had the thermometer down to 50° below zero in the open air; but a registering thermometer which we buried under about 2 feet of snow on the floe alongside, and left undisturbed the whole winter, never fell below 28°, or the freezing-point of salt water—so that unless the Wheat was exposed in some manner so that it could not be buried by either earth or snow, we could expose it to a much lower temperature here at home. So much for that experiment.

I would like to see some specimens of the Arctic flora brought to this country, to find out how they would weather our winters, as in their proper habitat they are always covered with snow, and here they would very often have to encounter severe cold without any such protection. In the North vegetation is so very rapid immediately after the disappearance of the snow, that one is apt to believe that some of the flowers actually ex-

pand underneath it. In Grantly Harbour I have gathered plenty of Onions about a foot long, which had half of that length covered with snow, and were in full flower by the time it was all gone; and about Cape Barrow, Icy Cape, and Wainright Inlet, the vegetation hardly ever seems to be checked, as the dwarf Alders and Willows, which are the only substitutes for trees thereabouts, are covered with fine plump buds under the snow in the months of January and February. Any ptarmigan (*Tetrax lagopus*) which we got during the winter appeared to live on these buds, as their crops were always filled with them. The Esquimaux, taking advantage of this predilection of the birds, snare them in great quantities by uncovering the bushes and affixing snares to them.

The great length of the summer days in those hyperborean regions serves in a great measure, in my opinion, to counteract the want of sun heat in ripening the numerous berries which abound there, otherwise the short summer would not suffice to get ready food for the various birds and beasts which visit the country.

If I happen to have any doubt about the effect of the climate on Wheat, I have none as to its effect on flour. Captain Beechy, in the ship "Blossom," buried an iron-bound cask of flour on Chamisso Island in the year 1825: in 1849 I was present when it was dug up by the crew of the "Herald," Captain Kellet; and, with the exception of a cake about three-fourths of an inch thick next to the wood, the rest of the flour when cooked was as good and palatable as if it had just come from the mill.—UNCLE ANDREW (in *The Gardener*).

### LIMATODES ROSEA.

I WAS interested in reading the article by Mr. G. Abbey in last week's number on winter-flowering plants, and was pleased to find that amongst Orchids *Limatodes rosea* is placed amongst those that are easily grown. I do not find it so; and Mr. Denning, Lord Loudesborough's gardener, who seems to grow and flower Orchids that puzzle everybody else, told me in conversation only last Wednesday week, that though nothing could surpass the beautiful soft rose of its flowers, it was a very difficult Orchid to grow and flower. I would thank Mr. Abbey very much if he would kindly say how he treats his plants as to temperature, compost, watering, resting period, &c.—J. DOUGLAS.

### PEAR SCALE.

IN the winter of 1870 I tried paraffin oil as a cure for Pear scale. I had a Muirfowl Egg tree very severely attacked by it. Seeing that paraffin oil was stated to be a complete cure for the pest I resolved to give it a trial, so I loosened all the branches from the wall and applied the oil with a painter's brush. The result was a perfect cure so far as scale was concerned, but the tree, an extra healthy one, was killed. I also know of another gardener who made the experiment with the same result. My motive for writing this is to warn others to be careful in using paraffin in the manner described. But I may state that I have used it with beneficial effects as a wash for fruit trees (in winter) in the following manner:—

To one gallon of water was added one gill of paraffin, working the whole well up with the syringe until it frothed like soap-suds, and with this I gave the trees a good syringing.—JAMES DICKSON.

### PLANTS AT THE CLOSE OF THE YEAR.

EVEN in winter we have a few lingerers left to cheer us in the season's gloom. Our beds and borders have lost some of their gaiety, but we have a few old friends left, and others are on the way. Plumbago capense is a capital plant for late autumn. *Zauschneria californica* we prize as a late autumn-blooming plant. Some of the Michaelmas Daisies still afford us sprays for bouquets and other decorative purposes, one of the best of the tribe is *Aster elegans*; *A. dumosus* is also a useful plant at this season. *Chrysanthemums* in sheltered places do us good service. *Viola odorata* in the open border has given us a supply of blooms for weeks past, and will do so for weeks to come; no doubt the hot dry summer has had much to do with the flowering now. Pansies sown in the spring are strong and coming into bloom, showing us their cheerful faces. *Viola Perfection*, *Lothair* and *Lutea grandiflora* are among our best and are very effective. *Lupinus nanus* still keeps on flowering. *Saponaria calabrica*, *Alyssum maritimum*, *Salvia argentea* and *Phlox verna* are cheerful still. Spring-sown

Snapdragons flower late in the autumn and are useful for cutting. Dandelions and Daisies are peeping up here and there. *Lamium album*, *L. maculatum*, *Geranium Andrewsii*, *Feverfew*, *Linaria Cymbalaria*, *Silene compacta*, the old Monthly China and other hardy Perpetual Roses, not forgetting Gloire de Dijon; Primroses, Polyanthus, Alyssums, *Arabis alba*, *Farsesia purpurea*, *Veronica Blue Gem*, *Leptosiphon roseus*, *Senecio vulgaris*, *Capsella Bursa-pastoris* bring up the rear of November's flowers.—OBSERVER.

### PAINTING FRUIT TREES.

JUDGING from the way that painting fruit trees is recommended and practised this operation must in many instances be considered as forming an essential part of the gardener's practice. It is generally under glass that painting is most generally prosecuted, Vines, Peaches, and Figs coming in for a very large share of it. Some of the ingredients used in painting might no doubt be very injurious to insects at the time of application, but the paint soon loses its strength, and before the trees are in leaf insects have nothing to contend against so far as the painting is concerned.

Too much dependence is often placed on painting. I have known instances where trees badly infested with insects received no further attention to eradicate them than being painted over, and when growth begun the insects were as plentiful as ever. To make paint effectual it should reach every corner and part, and not the upper surface of loose bark only, as is too often the case; but when the loose bark is cleared off and the inner bark well washed with soft soap and water it is quite impossible that any insect or any of their belongings can be left or find a place, and when they are thus removed there is no necessity whatever for painting. I have not painted a tree with the intention of killing insects for some years past, and insects have been much fewer than when I painted. The labour saved in not painting is considerable; and in the place of dirt everything is clean throughout the whole season. I found when the paint was put on thickly that it cracked in the summer time, and the crevices formed an excellent harbour for vermin.

I should like some of those who have been in the habit of painting their trees to discontinue it this winter, and wash thoroughly, leaving every part perfectly clean; when, after a season's experience, I am certain they would never be at the trouble of painting another tree.—A FRUIT-GROWER.

### SOME OF OUR NATIVE DECIDUOUS TREES.

As the merits of flowering shrubs of the deciduous class have been alluded to by a correspondent, would it not be worth while going a little further than he has done? Without decrying the claims of the many popular shrubs which he has named, I desire to put in a claim for some of the most common of our indigenous shrubs and trees, which often occupy the most unfrequented nooks and corners of our woods and coppices, and yet in themselves afford a display of beauty not always found in those that hail from a far-distant country. For instance, what can be more beautiful than the golden inflorescence of some of the Willows, which in some coppices give a tint of bright colouring seen quite a mile or more away, and at a time of year when flowers are always acceptable? In damp places the Willow very often overtops its neighbours, and its appearance is the more conspicuous. Some of the species are truly beautiful; I believe the male plant of one of the species is thought to be the most handsome, and the female of some of the others; the first-named not being very plentiful, but the latter very common. Perhaps someone will explain this. These Palms, as they are locally termed in most country districts, have in themselves a sort of poetic feeling attached to them, apart from their intrinsic worth as objects of beauty.

Following these we have others with flowers scarcely less showy—the Bird Cherry, or Hackberry of some districts, has a flower not much inferior to the imported *Deutzia*. And where is it possible to find any growth that will exceed that of the Elm when it is fairly out with its clustered flakes of inflorescence loading every particle of its numerous twig ends early in May? I have seen them used with advantage in an arrangement for dinner-table decoration.

Some other trees are also beautiful in their way. The wild Crab is not inferior to the cultivated Apple; while it is need-

less to point to the beauties of the May; poetic writers of all ages have never ceased breathing its praises; and many other of our most common trees give us forms of beauty peculiarly their own. The clusters of Ash keys exceed in beauty that of many an exotic plant for which high prices are paid; and the wild Briar is scarcely inferior to the Rose when it is seen struggling through a hedge or mass of undergrowth wood of any kind, neither is a solitary plant of it to be despised when hanging over a dry bank or other suitable place. There are many others of the common trees deserving notice. Even sprays of the common Beech look exceedingly well when in fruit, and the wonder is why what I may term the floral beauty of common trees has not been noticed before.—J. ROBSON.

### NOTES AND GLEANINGS.

THE donations promised towards the NATIONAL ROSE SOCIETY are as follows:—The Rev. Canon Hole, £5; Rev. C. H. Bulmer, £1; John Cranston, £5; Messrs. Cutbush & Sons, £2 2s.; Messrs. Paul & Son, £10; Captain Christy, £5; Herbert J. Adams, £5; John Mayo, £5; R. S. N. Baker, £5; the Rev. J. B. M. Camm, £5; E. C. Roberts, £1 1s.; H. C. Mayor, £2 2s.; W. E. Ball, £1 1s.; James McIntosh, £5; T. Francis Rivers, £5; Lewis A. Killick, £1 1s.; J. Mann, £1 1s.; B. R. Cant, £5; Edward Mawley, £1 1s.; Geo. P. Hawtry, £2 2s.; John Laing, £1 1s.; Charles Turner, £5; Herbert Bensted, £5; William Paul, £5; J. L. Curtis, £3 3s.; Maurice Young, £2 2s.; J. W. Parke, £1 1s.; *Journal of Horticulture*, £5 5s.; and George Prince, £5.

NEVER are GLADIOLUSES more admired than when flowering in conservatories from the present time until Christmas. In order thus to produce them it is necessary to plant largely corms of the common yet beautiful kinds *Brenchleyensis*, *Fanny Rouget*, &c., early in June. These produce spikes late in the season, and commence showing colour about the end of October. The plants should then be potted, or if they will not lift well, their spikes with foliage surrounding them should be placed in small bottles of water, and these be sunk in pots of soil. The new corms formed by planting thus late are necessarily small, and these should be planted early the following season to produce another supply of large corms. The spikes now unfolding are extremely bright and attractive.

WE regret having to announce the death of Mr. JOHN INGRAM, of the firm of Wood & Ingram, Huntingdon. He died on the 10th inst, aged fifty-four years.

At the Smithfield Cattle Show Messrs. Carter & Co., seedsmen of High Holborn, who recently held the extensive ROOT SHOW in the Agricultural Hall, had a spacious and tastefully arranged stand. It contained choice stocks of Turnips, Carrots, Potatoes, Onions, and Grasses in growth, Grass seeds, and a number of other things, the whole being grown from Messrs. Carters' seeds. Among the horticultural lots were some very fine Carrots, Parsnips, Onions, &c., in great variety. Of Potatoes were specimens of Carter's American Breadfruit, Improved Red-skin Flourball, and Porter's Excelsior.

THE following donations have been offered towards the fund of the southern branch of the NATIONAL AURICULA SHOW, and we are glad to learn that the Committee anticipate being able to provide a good schedule and to secure a good show:—James McIntosh, Esq., £2 2s.; Dr. Masters, £1 1s.; *Journal of Horticulture*, £2 2s.; Dr. Denny, £1 1s.; Mr. C. Lidgard, £1 1s.; Mr. Meiklejohn, 10s. 6d.; Francis Whitbourn, Esq. Loxford Hall, President, £5; Mr. Charles Turner, Royal Nursery, Slough, Vice-President, £5; Mr. E. S. Dodwell, Clapham, Hon. Sec., £5; The Crystal Palace Company, £10; Mr. Douglas, £1 1s.; Rev. H. Honeywood Dombain, £1 1s.; Mr. Laing, £1 1s.; Mr. Thomas Moore, F.L.S., £2 2s.; Mr. R. Dean, £1 1s.; Rev. F. D. Horner, £2 2s.; Richard Gortan, Esq., £1 1s.; Thomas James, Esq., 5s.; Mr. J. James, Isleworth, £1 1s.; Mr. H. M. Pollett, Bridgewater Gardens, Barbican, E.C., £1 1s.; G. F. Wilson, Esq., £1 1s.; Messrs. Cutbush & Son, £1 1s.

OUR correspondents who write concerning *Eucalyptus globulus* will doubtless be pleased to hear of *E. polyanthemos*, which is perhaps the hardiest of all. A fine tree is in a quite exposed position at Kew near the Museum. In the spring of 1874, when the young growths of forest trees were injured by frost and cold winds, it was quite untouched, though also in a growing state. In 1865, when 20 feet high, the top was killed

by severe frost, but from the base came several vigorous shoots which have since reformed the specimen, and now its glaucous leaves form a good contrast with the green of other trees. The original trunk measures 4 feet in circumference. *E. globulus* is not hardy at Kew, even with wall protection. *E. Gunnii* and *E. urnigera* it is said should be hardy in the climate of Paris.

— At a recent meeting of the LINNEAN SOCIETY, Mr. H. N. Moseley, of H.M.S. "Challenger," read a paper on the flora of Marion Island. This island possesses considerable interest from its isolation, and being within the antarctic drift. It is about 1000 miles from the African continent, 450 from the Crozets, 1200 from the desolate Kerguelen Island, about 2000 from Tristan d'Acunha, and 4500 from the Falklands, to which, nevertheless, its flora appears related. It is of volcanic origin, and snowclad. The rocks at half-tide are covered with *Darvillea utilis*, above high tide *Tillæa moschata* is found in abundance, and beyond the beach a swampy peaty soil covers the rocks, where there is a thick growth of herbage; this is principally composed of species of *Acana*, *Azorella*, and *Festuca*, the first of these three being the most abundant plant on the island, though the latter Grass is by no means scarce. The Cabbage-like plant *Pringlea antiscorbutica* is less profuse than at Kerguelen's Land. Some of the *Ranunculus* group are met with at water pools near the sea. Four kinds of Ferns were obtained; *Lomaria alpina* being the most numerous. Lichens are scarce, but Mosses in plenty form yellow patches, which stand out conspicuously midst the green vegetation, which rises to an altitude of probably 2000 feet. From the occurrence of *Pringlea* on Marion Island, the Crozets, and Kerguelen Island, and the existence of fossil tree-trunks on the two latter, the author surmises an ancient land connected between them.

— THE Paris journals announce the death of a famous ORANGE TREE in its 455th year, known under the name of Grand Bourbon or Grand Connétable. In the year 1421 the Queen of Navarre gave her gardener the seed at Pampeluna. Thence sprang the plant, which was subsequently transported to Chantilly. In 1532, however, the Constable of Bourbon (Lord of Chantilly) having sided with Charles V. against Francis I., his goods were confiscated, and along with them the Orange tree, which was duly sent to Fontainebleau, whence, in 1684, Louis XIV. transferred it to Versailles, where it remained the largest, finest, and most fertile member of the orangery, its head being fifteen metres round, and the trunk seven metres high.

— At the last meeting of the Floral Committee at South Kensington we noticed two plants of PLUMBAGO ROSEA, as exhibited by Mr. Ollerhead from Sir Henry Peek's collection at Wimbledon House. We have since seen this Plumbago growing at Wimbledon, and do not hesitate to say that the effect produced is one of extraordinary novelty and beauty. The Plumbagos are growing in 8-inch pots placed about 4 feet apart, at the foot of a back wall of a heated pit devoted to the cultivation of Melons and Cucumbers. The plants are trained on the wall, and cover it in every part with fresh green foliage and a profusion of rosy-pink racemes of flowers, producing a charming effect. The plants arch gracefully over the path when they reach the shelf at the top of the wall. The wall is 60 feet in length, and its present mode of decoration reflects great credit on Mr. Ollerhead. The effect of this Plumbago thus grown is unique and beautiful.

— "J. A." writes—"I purchased a plant of the new DOUBLE POINSETTIA, and I now possess half a dozen small plants showing their bracts, but they do not show any signs of coming double. How is it?" To this we reply, that plants thus treated ought not to be expected to produce a multiplicity of heads. Grow a few plants vigorously, not weakening them by repeatedly stopping them and striking cuttings, and they will reward with gorgeous heads of brilliant bracts. This is only a grand plant when well grown, and then it is indeed most striking.

— A WRITER in the "Journal of Chemistry" has thus referred to the MEDICINAL USE OF CELERY:—"I have known many who from various causes had become much affected by nervousness, and who by a moderate daily use of the blanched footstalks of Celery as a salad they became as strong and steady in limb as other people. I have known others so nervous that the least annoyance put them in a state of agitation, and they were in constant perplexity and fear, who were also effectually cured by a moderate daily use of blanched Celery as a salad.

Everybody engaged in labour weakening to the nerves should use Celery daily in the season, and Onions in its stead when not in season."

— IN order to prevent the introduction of the COLORADO POTATO BEETLE amongst Potatoes imported from the United States or Canada, instructions have been issued to the collectors of customs at the various ports of the United Kingdom, that Custom House officers are to look out for the beetle on board vessels, wharves, quays, sheds, or packages landed from vessels, and instantly destroy it. To aid them in identifying the beetle a lithographed sketch and description of it have been issued.

— THE PROPAGATION OF HYACINTHS FROM LEAVES has been lately referred to by Mr. Barleben, gardener to the Berlin University. Mr. Barleben's plan is to take off the leaves when in full vigour, cutting them off as close to the bulb as possible, and insert in a saucer of leaf soil and sand, placing in a frame or greenhouse, and in eight or nine weeks bulbs will form at the base of the leaves. Many years ago an English gardener increased new and rare Hyacinths in a similar manner, but found it necessary to secure a portion of the scaly bulb with the base of each leaf.

— MR. McLEOD, who was lately gardener to the Marquis of Lothian at Newbattle Abbey, has been appointed Superintendent of Public Parks and Gardens of Edinburgh, and we are informed also that Mr. Graham has been appointed Superintendent of the gardens at Hampton Court. The experience and ability of these gardeners are sufficient to ensure the successful management of the important gardens placed in their keeping.

— MR. MOWBRAY, gardener to the Earl of Leven and Melville, writing to us from Falmer, near Slough, on EARLY VEGETATION, states—"Should the weather continue open and mild I shall have several Peach trees in bloom shortly; the buds are ready for opening now, and are as forward as they ought to be in February. The Cherries are equally as forward. It was the mild warm weather in September that swelled the buds, and they received no check in October. I think we have scarcely ever had a milder autumn than this—in fact, I do not remember ever seeing the fruit trees as forward as they are about here at this period of the year. The agricultural crops of this district are also in active growth. Several pieces of winter Oats nearly cover the ground."

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

THE weather is so very wet that but little can be done on the ground. Such operations as digging, ridging, and even trenching cannot be performed with any degree of comfort to the men employed or benefit to the ground. In such weather Onions stored in lofts, or roots and Potatoes stored in sand in back sheds, can be overhauled and all decaying bulbs or tubers be removed to prevent the spread of decay. It is not possible to wheel barrowloads of manure in such weather without making much extra work by cutting up the ground. Should frosty weather set in advantage may be taken of it to wheel manure on to the quarters. A not uncommon way with some gardeners is to leave it lying on the ground in barrowloads. This is probably the worst way in which to treat manure intended for the garden. It is preferable to spread it out evenly over the ground, or better still, to make a large heap by putting together as much as will manure the quarter, and throw a little soil over it.

Should frost set in tender vegetables will suffer, owing to so much wet, and the weather being so mild has caused them to make much growth, which further makes them more than usually tender. Celery and Cardoons should be protected with straw—long littery stable manure is sometimes used. It is thrown loosely over the sides of the trenches, and some of it over the leaves. A much better plan is to use clean straw of any sort; let the top end of the straw be placed upright against the sides of the Celery trenches, and so that it meets over the tops of the plants. Very little straw is necessary, as if there is too much the air will not circulate freely amongst the plants. The straw is easily kept in its place by stretching a cord along the trench near the top, and affixing the cord to stout pegs inserted in the ground at intervals along the rows. A little soil may be thrown on the lower end of the straw.

Lettuce plants in frames require frequent attention in order to remove any decaying leaves. In wet weather the lights require to be tilted both back and front, so that a constant circulation of air may benefit the plants. Cauliflower plants require

similar attention, and when frosts set in the ground around hand-lights should be covered with manure. It is not necessary to throw any protecting material over the glass.

#### VINERIES.

Except Lady Downe's, Grapes generally are not keeping well, owing to the damp atmosphere, although with us Royal Vineyard and Paul's Waltham Cross have kept hitherto, and suffered but little from damp. We have not yet had fruit upon Pearson's Golden Queen, and cannot say from experience how that sort will keep. It is said to be a good setter, and is also recommended as a good late Grape. Royal Vineyard and Waltham Cross are both of them rather shy setters at Loxford. We keep up the temperature to 70° when the fruit is setting, and nearly all sorts of Grapes that are usually grown set well in this temperature. There is no difficulty with Royal Vineyard if a small globule of moisture which gathers on the stigma is dispersed, and this is done by drawing the hand gently down the bunch when it is in flower.

The importance of removing decaying leaves and berries has been frequently urged, and it is dangerous to allow the temperature to fall much below 40° at night. Ventilate as much as possible, except in wet, thick, or foggy weather. A draught of air through the house at such times carries destruction to the berries.

Forcing should be carried on steadily. Until the buds start we do not care to have the night temperature much over 50° until a few small leaves are formed. After that the night temperature may be gradually raised to 60°, and in a week or two more to 65°, and in the case of a house devoted to early Muscats to 70°. We keep up a good supply of atmospheric moisture, but do not syringe after the leaves are formed. Vines in pots that have been started in November for the earliest Grapes will now have started into growth, and as it was recommended to plunge the pots in bottom heat the roots will be making as much progress as the canes are doing above ground, so that, if necessary, a higher temperature may be kept up in the earlier stages of growth. Great care is necessary in order that the Vines may not suffer from want of water.

#### ORCHARD HOUSE.

The fruiting trees are still out of doors in the plunging material. Soaked they must be at the roots with wet, but we have not observed that injury by this cause has been done in previous seasons. When sharp frost sets in, if the trees are not removed to the house by that time, some dry cocoa-nut fibre refuse placed over the leaves in which the pots are plunged will keep the frost from the roots, and this is necessary, as they make considerable growth during the winter months, and it is not well to check this growth.

Young trees ought now to be potted to form fruiting trees for next season. This may be done by purchasing "maiden" trees—that is, those which have made but one year's growth from the bud. They may be purchased in any large nursery at a cheap rate, and if well treated make good fruiting trees for next year. Some of the large trade firms grow trees in pots, and those who intend "taking to" orchard-house trees in pots and who do not care for the trouble of managing one-year-old trees for a season, would do well to purchase such trees ready trained for fruiting. A season is gained by doing so, and the trade can do the work far better and cheaper than any gardener or amateur can. Strawberry plants have been removed to the shelves near the glass, and when the Chrysanthemum plants are removed no time will be lost in taking in the trees.

#### PLANT STOVE AND ORCHID HOUSES.

Although at this season of the year nearly all the objects in these structures are passing through their resting period, still the temperature of the house in many instances must not be allowed to fall below a certain standard, else heat-loving plants suffer. In the Pine house where are several different species and varieties of *Ixora*, it is found that the plants will not pass safely through the winter months in an average night temperature of 60°. *I. Williamsii* was the first to show signs of distress by some of the leaves falling off, and others showed blotches of decay, but on the plants being removed to a house with 5° more heat a change for the better was speedily apparent. *I. javanica*, *I. Colei* and others do not show any signs of distress as yet, but it is evident that all this class of plants including *Dipladenias* ought to be wintered in a house where the temperature does not fall below 65°. Other plants usually grown in the stove do better with 55°, or from 55° to 60°. However, by far the largest number of our readers have only one, or at most two houses for the different classes of plants; when this is the case much can be done by placing the heat-loving plants at the warmest end of the house, and those that require cooler treatment in the position most suitable for them. Any observant gardener will bear us out in saying that a plant will do exceedingly well in a certain position. Remove it from that place to another in the same house and it refuses to thrive; take it back to its old position and an improved condition is evident.

A very good form for a house intended for a miscellaneous collection of stove plants is a span-roof, wide enough to admit of

a centre pit for fermenting material, and a slate platform round the sides and ends about 2 feet wide. The centre of the house will be a few degrees warmer than the outside, and if the pit is filled with tan or oak leaves a genial lasting heat will be obtained, and if it does not rise above 85° or 90° the pots may be plunged to within a few inches of the rim. Under such circumstances the plants would not suffer in a slightly lower temperature than would otherwise be required. Then another class of plants should be arranged on the side platforms, beginning with those requiring most heat at the warmest end. In our stove, 28 feet by 20, there is a difference of 5° between the temperature at the end nearest the boiler and that furthest removed from it.

Orchids require considerable attention during the winter months. Very little water is necessary at the roots, but the drying-off system may be carried too far even at the dullest period of the year. *Cattleya Warnerii* is just now starting into growth, but it is not necessary on that account to do more than keep the compost moist. If the plants are potted in turfy peat and sphagnum allow it to become quite dry before watering; although the pseudo-bulbs are being formed for next season, the roots will not be in an active state until midsummer. The same may be said of *Lælia purpurata*; the growths are further advanced than those of *Cattleyas*, but the roots are not yet productive. All other *Cattleyas* and *Lælias* of the same class require similar treatment. Those on blocks and brackets will require more water according as the roots have less or more material around them. *Odontoglossums* in the cool house require a considerable supply of water, as many of them, such as *O. crispum*, *O. triumphans*, *O. odoratum*, *O. cirrhosum*, and others of this section, are just making their growth. They do not require a high temperature; from 45° to 50° is quite sufficient; but the glass ought to be washed quite clean, and must not be allowed to become obscured. After a day or two of our thick London fogs the glass outside may be washed with a syringe or garden engine. Some of the *Masdevallias* are also making their young growths, and the plants require very similar treatment to that of *Odontoglossums*. If any slugs are in the house they must be searched for after it is dark at night; one of them may destroy at one meal a plant worth many pounds. There had been no trace of slugs in our cool house for months until one night a strong growth of *Masdevallia Veitchii* was observed to be eaten off. The intruder was caught next night as soon as it was dark. Had no search been made for an hour or two perhaps another growth would have been destroyed. Slugs are also very fond of eating through the stems of *Odontoglossums* just coming out of their sheaths. The paths and stages of Orchid houses ought to be damped over at least once every day.—J. DOUGLAS.

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

NEWCASTLE-UPON-TYNE. March 21st and 22nd, 1877. Messrs. J. H. French, Benwell House, and J. Taylor, Rye Hill, Hon. Secs.

LEEDS (Spring Show). April 2nd and 3rd. Mr. A. Walker, Neville St., School Close, Leeds, Hon. Sec.

WISBECH. June 28th. Mr. Charles Parker, Hon. Sec.

TONBRIDGE. July 18th. Mr. W. Blair, Sec.

ISLE OF THANET. August 30th. Mr. C. D. Smith, Hon. Sec.

### TO CORRESPONDENTS.

BOOKS (B.).—The "Garden Manual," price 1s. 6d., can be had free by post from our office.

FUNGI (C. B. P.).—The specimens were smashed by the post-office punches.

CARPET BEDDING PLANTS (G. B. T.).—After the reservation you have made we cannot think of more than three which you may raise from seed—namely, *Oxalis tropaeoloides*, *Cerastium tomentosum*, and *Mesembryanthemum cordifolium variegatum*.

CHILIAN BEET (*Beetroot*).—It will throw up flower stems next spring, but the roots should be at once transplanted to their seedling quarters—not taken up and stored until spring.

TARRING TREE TRUNKS (*Royal Oak*).—The gas tar will not do the trees any good, but it may save them from being denuded of the bark by hares, rabbits, or horses, if the latter have access to the trees. We have not noticed any great injury result to the trees from coating them with gas tar, but we do not advise the use of tar except as a preventive of hares, &c.

TEMPERATURE FOR ORCHIDS (*Rus*).—*Cælogyne cristata* should now be kept dry, and in a cool stove or warm greenhouse. It is one of the cool Orchids, being from Nepal; it would succeed probably in a not very airy greenhouse. *Dendrobium formosum* does not need a higher temperature in winter than an intermediate one—i.e., a cool stove or warm greenhouse. *Poinsettias* require a temperature in winter of 55° to 60° at night, and 60° to 65° by day, with a rise to 75° from sun.

HOthouse ARRANGEMENTS (*Rosa*).—Your term "hothouse" is very indefinite. If you mean a stove, which is a common acceptance of the term hothouse, you will require four 4-inch hot-water pipes—two flows, with their returns along three sides of the house, or better still all round, excepting of course the doorway. We should have shelving along two sides and one end of the house, omitting the doorway—3 feet wide, and beneath this shelving place the hot-water pipes. At the other end of the house we should arrange a rockery for Ferns, with a base of about 8 feet; a walk all round the house (5 feet) will give you a central bed of some 9 feet in width. The path-

way would of course need to be carried across the end next the rockwork, and beneath this the hot water could be taken in an open flue covered with iron grating forming part of the pathway. You could arrange for a "sloping bank" of rockwork all around the house for Ferns, and take the hot-water pipes in an open flue with ornamental grating over forming part of the path, and dispose of the centre as a bed or stage for plants, which should be formed of stone or slate.

**ORCHIDS FOR NOVEMBER AND DECEMBER (J. S. W.).**—*Calanthe vestita* var., *Zygopetalum Mackayi*, *Odontoglossum Alexandrs*, *O. grande*, *O. insleyi*, *leopardinum*, *Dendrobium nobile*, *D. Wardianum*, *D. chrysanthum*, *Laelia anceps*, *Lycaste Skinneri*, *Cypripedium niveum*, and *C. insignis*. Nearly all Orchids will, whilst in flower, endure the atmosphere of a conservatory kept at about 50°.

**GARDENIA FLORIDA DYING (An Apprentice Gardener).**—We should attribute the death of the plant to having had all the soil removed, and the consequent loss of fibrous roots. The daily syringings were not likely to mend matters in such a case, as the fresh soil would be made too wet.

**PROPAGATING EPACRISSES, HEATHS, AND CAMELLIAS (W. P.).**—*Epacris* and *Eriacae* are propagated by cuttings of about 1½ to 2 inches in length. The tips of the shoots when of that length are inserted in pots half filled with drainage, some rough peat placed over it, the pot filled to within half an inch of the rim with fine sandy peat, and the remainder with silver sand pressed firmly; water thoroughly, and a few hours afterwards put in the cuttings, and cover them with a bell-glass, placing in a cold pit or frame, shading from sun. Camellias are increased by grafting upon stock of the single kind. Cuttings for stocks require to be of the ripe wood, inserted firmly in sand, kept in a close frame for a month or six weeks, and then placed in a gentle bottom heat. The plants you name can be bought from the trade growers more cheaply than they can be propagated in private gardens.

**REPORTING CAMELLIAS (J. H.).**—The potting should not be done until the flowering is very nearly over. We do not pot ours until the buds are set, generally in August up to early September.

**DRACENA FLOWERING (G. S.).**—Keep the plant in the same temperature, and when it flowers keep the atmosphere dry, and fertilise the flowers. The Fern No. 4 is *Cheilanthes lundigeri*, and No. 6 appears to be *Adiantum concinnum* latum.

**PETALS FALLING OFF CUT FLOWERS (A Constant Reader).**—Drop into the flower, so as to run down to the bases of the petals, very thick gum water.

**APPLES (Senex Coryius).**—We have no doubt that the names you have attached are correct; but they are local names, and the varieties are not known out of the cider districts.

**APPLE AND PEAR SPRAYS (L. I. K.).**—They are all attacked by canker. The roots have descended too deep in a clayey soil. The trees should be lifted, and the roots kept near the surface.

**RAISING FLOWER BEDS (Alpha).**—Taking up flowers for your purpose at this season will not injure them. Cocoa-nut fibre refuse is not a good manure, and covering the plants with it 2 inches thick would probably injure some of them.

**MAKING AN ASPARAGUS BED (A. C.).**—This is best done at the end of March or early in April, being the best time also for planting. If the ground is common loam and well drained, or having a subsoil of gravel or chalk, nothing more is needed than to trench the space intended for the bed, and to mix with the soil as much rich thoroughly decayed dung as can be worked-in. Have only two rows of plants in each bed, as this enables them to be cultivated and cut from easily. Set the rows out 2 feet apart, stretching the line, and drawing with a hoe a drill on each side of it sufficiently deep for the roots to be extended on each side of the little ridge which is thus left between the two drills, and on which ridge the plants are placed. Their roots being equally divided on each side, nothing more is required than filling up the drills with a hoe or rake. The plants should be chosen when they have started into growth 2 or 3 inches; they should be forked out carefully, and their roots not allowed to get dry after being taken up. No heads should be cut the first year after planting, and very few the second.

**PEARS FOR WALLS (F. L.).**—West aspect—Marie Louise, Van Mons Leon Leclerc, Beurré Diel, East aspect—Beurré Bosc, Winter Nelis, and Glou Morceau. Tea Roses will do well on a low wall with west aspect.

**COVERING VINE BORDER (J. Thomas).**—In wet districts and in wet seasons it is as well to place boards over the Vine border to throw off superfluous wet, but the covering must be watertight, and some arrangement must be made to drain away the water falling from the boards, else it will only be carrying water from one part of the border to run it on to the other.

**MANAGEMENT OF PEACH TREES (Young Beginner).**—If you want to gather Peaches in April or May, the house must be started at once (see last number, page 495). You will not be successful with greenhouse plants in the same house. The *Chrysanthemums* may be placed in a cold frame, or failing that in a sheltered place out of doors.

**TANK FOR BOTTOM HEAT (Staines).**—Two 4-inch pipes will be sufficient. Plunge the Pines in tan.

**STANDARD CHRYSANTHEMUMS (B. E.).**—Insert the cuttings now or early in February in a little bottom heat. Grow the plants on without any check, and stop them at the required height. The succeeding growths must be trained into shape by fixing a ring of iron wire the height of the plant and about 2 feet in diameter. Cultural directions are given in the present number.

**LADY DOWNE'S GRAPES CRACKED (L. D.).**—What you say in your communication is very feasible; but you also say that they began cracking immediately after heavy rain, therefore there can be no reason to doubt but that the wet border is the cause, and the wet close atmosphere would also aid in the destruction of your crop.

**VINES FOR LATE VINERY (Idem).**—Lady Downe's, Gros Colman, Alicante, and Pearson's Golden Queen. The two best Peaches for your purpose are Early York and Royal George.

**POTATOES FOR EXHIBITION (J. R.).**—Omit King of Potatoes and Melbourne Hero, and substitute them with Lapstone. In the class for rounds replace Early Handsworth and King of the Earlies with Schoolmaster, a splendid sort sent out by Mr. C. Turner of Slough. The true Early Handsworth is one of the earliest, if not the earliest round Potato; but this is a different variety from many of the dishes exhibited at the Alexandra Palace under that name.

**PROPAGATION OF PHILODENDRON (One in a Faw).**—This plant may be readily propagated by division of the roots, or by cuttings of short young

growths. The cuttings should be inserted in sand in a pot and placed under a bell-glass. It is a stove plant.

**AMERICAN BLACKBERRIES (Inquirer).**—The Lawton Blackberry can be bought of the raiser, Mr. William Lawton, New Rochelle, New York, U.S.A.; or from Messrs. Ellwanger & Barry, whose advertisement appears in the Journal.—H. S. J. It can also be purchased at Messrs. Veitch & Sons' nurseries, Coombe Wood.

**STONE-COLOURED PAINT (C. Alley).**—Mix stiff ground white lead with a little spirit of turpentine into a smooth cream, adding linseed oil and more turpentine until of the desired thickness; then thoroughly mix with it a little powdered burnt umber to impart the stone tint.

**FEVER PLANT (J. R.).**—This is one of the popular names of *Eucalyptus globulus*.

**ROSE BUD (An Interested Reader).**—No one could tell the name from the specimen sent.

**CUCUMBERS FOR FRAME CULTURE (E. B.).**—Manroe's Duke of Edinburgh is a very free-bearing and fine-flavoured kind. Master's Prolific is also first-rate; both have fruit about a foot in length; and for size Tender and True is very good. Telegraph is also very desirable, but for general frame culture and everyday use we prefer the first-named variety. We should not sow until the early part of February.

**DESTROYING WEEDS ON GRAVEL WALK (G. Foster).**—Dissolve 1 lb. of powdered arsenic in three gallons of cold water, stirring until it boils, then add seven gallons of cold water and 2 lbs. of crushed soda. Stir the whole well whilst boiling, and with a rose watering-pot apply to the walks in dry weather from March to May. An inclining board should be placed so as to keep the hot liquid from the grass or Box edgings. The quantity named is sufficient for 25 square yards. Carbolic acid has been recommended to our correspondent for the purpose. We should be obliged by particulars as to the quantity and mode of application.

**POMPON CHRYSANTHEMUMS (P. P.).**—Perhaps the best white, dark, and yellow rather late varieties are Mdlle. Marthe, Bob, and Golden Circle.

**NAMES OF FRUITS (G. Stone).**—The Pears are—105, Vernalis; 172, Beurré Clairgeau; 65, Duchesse d'Angoulême; 150, Catilae; 170, Vicar of Winkfield; 97, Suesette de Bay. (James Lessels).—Pears—1, Glou Morceau; 2, Colmar; 3, Catilae. Apples—1, Autumn Pearmain; 2, Braddick's Nonpareil; 8, Sturmer Pippin. (C. B.).—It is possible the Apple is a seedling, but it is not one which is possessed of merit superior to many others in cultivation.

**NAMES OF PLANTS (W. P.).**—1, *Salicigella denticulata*; 2, *Sedum acre* (E. B. B.).—*Begonia Weltonensis*. It is very pretty from its foliage and flowers at this season in a warm greenhouse or cool stove. It belongs to the natural order Bignoniaceae, and Class 21, Monocotyledon, Polyanthia, Linn. (A Young Gardener).—We cannot name plants either from leaves only, or that are florists' varieties.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### CAN A POULTRY FARM PAY?

I MUST apologise to Miss Weston for not having answered her letter of November 23rd before this, but my time of late has been so much occupied. Even now I can only write very briefly, but will do so more at length in a week or two.

In the first place, what I wanted to elicit was the opinions and advice of others, and I am delighted to find the matter taken up by Miss Weston; and I only hope that Mr. Bailey, Mr. F. Wragge, and other large breeders will come to the front and aid in the work. I can assure Miss Weston that, so far from wishing to take her letter in bad part, I am only too glad to find that others are interested in such a work as I propose.

I would particularly ask Miss Weston to read again the last three lines of my letter in your impression of November 9th—"Many of these supposed items may not turn out facts; but I think enough has been shown to infer that there is fair ground to expect with due care and supervision there should be a fair profit."

Now a few words as to the figures. I must make a few corrections. On making inquiry as to land I find I can get land very suitable at 10s. per acre. Thus it stood before: Thirty acres at 30s. per annum per acre, £45. Now it stands: Thirty acres at 10s. ditto, £15. Again as to markets. Inquiries preliminary to arranging contracts show that I can throughout the year obtain from 8s. to 9s. per 120 eggs. The prices of fowls, chickens, &c., would be slightly in advance of that stated. As to hatching, I do not expect fifty hens to do all the hatching. The fifty hens are to be kept chiefly on that account; but as I expect them to lay some eggs as well, so do I expect my other two hundred hens to do some hatching as well as lay eggs. Besides this, I can hire temporarily sitting hens when required.

Now as to Brahmas and Houdans, which are the breeds I have kept and now intend to use (I have given up Redcaps), I found for many years that I had over five thousand eggs from about forty hens and pullets. During that time I entered every day the number of eggs received during each year, and weight and number of birds killed during the same period. I cannot just at present obtain this book to give extracts, but will do so when I can. As to breeding, one of my axioms is that you cannot expect more than eight birds out of a sitting of twelve eggs.

After consulting markets, train arrangements, &c., I find some figures to alter. Some I have mentioned, others I hope to do in a week or so. Finally I may say that I never expected to see a balance in favour of the undertaking such as may casually be deduced from the figures. I purposely omitted to draw a balance

also very good. In Dutch there were about five that were nearly perfect, but all the rest were more or less indifferent. It is seldom such a class of Belgian Hares is seen by the fact that the grand doe usually shown by Mr. Robinson was only highly commended. The two winners were almost equal, the first only beating in pencilling or ticking. In the Variety class Silver-creams won. The first in the Selling class was a Silver-Grey with a slight tendency to be mealy, but very even; and second a Grey-and-white Lop doe, 2½ by 4½. The class was large, and many others were noticed.

THE seventeenth annual Show of the Leeds Smithfield Exhibition was held on the 5th, 6th, and 7th inst. The entries numbered about 830. The show room was crowded every evening, and the receipts were larger than in any previous year.

*Pigeons* were in pairs, and this being rather unusual the entries were not as large as would have been the case if shown singly. In some cases the awards were ruled by the matching, one good bird being spoiled by a bad one, throwing the pen out, as in the case of the Carriers; the hen was a gem, but the cock bad in eye, the chance of the cup was thrown away, the cup in this case going to a grand pair of Yellow Dragons, which for colour and matching could not be surpassed. Pouters were good, but the pens were too small; when removed to larger pens while they were judged the birds had quite a different appearance. First were Blues, the cock superior, but hen somewhat backward. Second Blacks, a well-matched pair, both good in length of limb. Carriers not good. First Duns and second Blacks. Tumblers, first a well-matched pair of Almonds, second and third also good Almonds. Long-faces, first Black Balde, second Yellow Muffs. The Mottles not good. Owls were a fair lot. First Blue English, and second White Foreign. Pen 690 (Silvers) were a good well-matched pair. Jacobins were a capital class, there being little to choose between the first and second-prize winners, both Reds, the first rather short in face. Pen 699 (Blacks) contained an excellent bird. Turbirts were rather irregular. First Blues and second Reds. Fantails a good class, but the pens far too small to show them. Barbs poor, except the winners. First Reds and second Blacks. In Nuns there were no good pairs with the exception of the winners, but one pen contained a grand hen. Dragons, first and cup for the best pen in the Show, Yellows. Second Silvers with black bars. One pen of Blues were good, except that they were too soft and fleshy in eye. Antwerps, Long-faced, first Red-chequers and second Duns, no others coming near these in quality. Short-faced were a large class. First Silver Duns and second Red-chequers. Pen 767 contained a hen quite equal to the first winners, but the cock was not good. Magpies a very good class. First Reds and second Yellows. Swallows poor, except the winners. In the Variety class first were Pigmy Pouters, second plain Ice Pigeons. This was a very good class. In the Selling class first were Blue Pouters and second Red Turbirts.

*Rabbits* were a grand collection—the best, in fact, that has ever been seen at Leeds, the entries being about 130, the medal going to a Silver-fawn Dutch, one of the most evenly marked Rabbits we have seen for a long time. In Lops, which was a class that measured well, were—first a Sooty-fawn of grand style and carriage, 22½ by 4½. A Fawn-and-white doe, 22 by 5, was second; this was quite young and very promising. Pen 433, a Fawn-and-white, 22½ by 4½, was thrown out, its legs being crooked. Silver-Greys a good class, very even in body, but the silvering not quite perfect. Himalayans a good class, the first very dark in points, the second being much inferior. Angoras a capital lot. First a very fine-woolled specimen and good in size. Second very long in wool. Many others were

JUDGES.—Poultry, Game, and the large varieties: Mr. R. Teebay. *Hamburghs* and *Bantams*: Mr. A. Fielding. *Pigeons* and *Rabbits*: Mr. E. Hutton.

OVER nine hundred pens were exhibited, of which number five hundred were poultry, and among them birds of rare excellence that have been to the front at the Crystal Palace. The cup *Dorkings* were worthy of the county, and we have rarely seen so many good birds brought together. *Cochins* were good for a north of England show, Mrs. Christy taking first honours with a fine pair. *Brahmas* were good, especially the Lights, and they mustered forty-six pens. To Miss E. Shuter was awarded the jardiniere for a good pair of Darks. Light pullets had a cup to themselves, which was won by a good pair. *Game* were a good lot, the cup going to Mr. Foster for pen 149, but we did not like the hen. Pen 168 contained some very good Duckwings, which took the first, and a good pair of Piles had the second prize. *Hamburgs* mustered nineteen pens; as a class we did not consider them good. The majolica vase was awarded to very good pair of Silver-spangles, which were quickly sold at the catalogue price. The *Hamburgs* were not in a good light, and we consider not well judged. *Houdans* were not very numerous, but particularly good. We missed the cordial shake of the hand of our old departed friend Dring. *Crèves* were a small class of only four entries; *Spanish* also a small class. *Bantams* were very numerous and a good class. Game, any other variety, the first-prize birds were good Piles. Black Bantams were very good. In Bantams, any other variety, the first were very good Silver Sebrights. In Any other variety of fowl La Fleche took first, Golden Poland second and third, and Sultans fourth. The were only seven entries and four prizes in this class. *Ducks* were a grand lot of birds, the cup being won with a first-class pair of Rouens. In Ducks, any other variety, first were Pekins, second Pintails, third Carolinas. *Geese* were not a good class. *Turkeys* were a grand show, second only to that at the Crystal Palace.

**Pigeons** mustered 197 pens of very excellent birds. We are sorry to hear Dr. Bowes lost a valuable bird, being either misplaced or abstracted. He has advertised a reward for the valuable White African hen Owl stolen from pen 603. We are authorised to state the bird is marked and can be identified. Antwerps seem the favourite breed in Kent, and were largely represented. *Canaries* were also both numerous and of unusual excellence.

Mr. Ladd, the Hon. Secretary, exerted himself to the utmost, and nothing was wanting to make this, the first Kent County Canterbury Show, a great success. All missed and regretted the absence of Mr. Mount, who through ill-health has been obliged to resign those arduous duties which he as Secretary so well hitherto discharged.

**POULTRY.**—**DORKINGS.**—Coloured.—Cup and 8, R. Cheesman. 2, E. Rice. *Chickens.*—1 and 2, E. Cheesman. 3, E. Rice. *Silver-Grey.*—1, Miss S. A. Hodgkin. 2, T. Wotton. 3, R. Cheesman. *Chickens.*—Extra Cup, C. Ratcliffe. 2, Major W. Plummer. 3, E. Cheesman. *White.*—1, Boulding. 2, Cheesman. *Any other variety.*—1, R. A. Boissier. 2, Major W. Plummer. 3, C. J. ### DORKING POULTRY SHOW.

The seventeenth annual Exhibition was held at the Town Hall on the 7th inst. Dorking is thoroughly Dorking in its poultry Show; seventeen classes out of thirty were devoted to this variety. Seven classes were "open to all England." Why are the doors closed to Scotland and Ireland? Ten-guinea cups often induce the sister countries to send birds distances equal to Dorking. The Coloured classes contained a superior collection, the first cup going to a pair of old birds belonging to the Rev. E. Bartrum. The cock was slightly out of condition, and we thought the hen a little oval in the back. Second (Parlett) a good pen, but the cock a trifle coarse in comb, and we detected a corn on the left foot, which doubtless lost him the first place. In young birds Mr. Taylor was first. Cockerel very sound in feet, but we fancied he was a little up on the back; pullet moderate. Second (Barnell) a pretty cockerel, matched with the best pullet in the Show. Blue or Speckled.—Old birds moderate, young only six entries. Cup (Barnell), a good pair of chickens. We hope this cup will be continued, and that it

will induce other breeders to cultivate this most useful but neglected variety. Silver-Greys.—The entries were above the average. White, only the two first were good.

**LOCAL PRIZES.**—Here the competition was restricted to an area of twelve miles from Dorking. The Dorking classes were creditable in quality, well filled, and the prizes widely distributed enough to show that in this district a very general interest is taken in the variety that bears the name of the town.

The other classes, with one or two exceptions, contained specimens that could not have created a very favourable impression upon novices of the variety they pretended to represent. Why not widen the circle? The Town Hall is a splendid building for the purpose, Dorking well situated, and a show might be established worth a journey to see.

**POULTRY** (Open to All England).—**DORKINGS.**—Coloured.—*Cock or Hen.*—Cup, Rev. E. Bartrum. 2, F. Parlett. 3, G. Ellis. *Chickens.*—1, J. Taylor. 2, T. C. **JUDGE.**—Mr. M. Leno.

### WATFORD POULTRY SHOW.

The annual Exhibition of poultry in connection with the West Herts Agricultural Society came off on the 11th and 12th inst. The Hall in which the Show was held is probably one of the best in the kingdom of its kind, and when lighted up at night had a brilliant appearance. The competition was confined to the county of Herts and a radius of twenty miles from Watford. The Geese and Turkeys always muster here in great force, and the Judge declared that the cup pen in the Turkey class were the best he had ever seen. There was a large entry of Dorkings, and the quality of these classes appeared to be in advance of former years. Mr. W. Tegetmeier was Judge, and his awards appeared to give satisfaction.

**POULTRY.**—**DORKINGS.**—Coloured.—1 and Cup, Rev. E. Bartrum. 2, Lord Chesham. 3, Lord Ebury. *White or Silver.*—1, C. Sneewing. 2, Miss M. J. L. Smith. 3, Mrs. Bealey. **COCKS.**—*Partridge.*—1 and Cup, Lord Chesham. 2, J. Hadley. 3, G. Bentley. *Any other variety.*—1, 2, and 3, C. A. Barnes. **BRAMA POOTRA.**—*Dark.*—1, J. Long. 2, D. Ford. 3, W. J. Jarvis. *Light.*—1 and Cup, J. Long. *Game.*—1 and Cup, G. Bentley. 2, C. A. Barnes. 3, R. Douglas-Sharps. **HAMPSHIRE.**—*Spangled.*—1, J. Long. 2, G. Bentley. 3, W. Chappin. *Pencilled.*—1, J. Long. 2, Lord Ebury. **BANTAMS.**—*Game.*—1, J. J. Long. 2, W. Boucher. W. Wilson. 3, G. Bentley. *Any other variety.*—1, Lord Chesham. **ANY OTHER BREED.—1 and Cup, W. Hitchcock. 2, Miss M. Clutterbuck. 3, P. Clutterbuck. *Aylesbury.*—1 and Cup, Lord Chesham. 2, Miss M. Clutterbuck. 3, P. Clutterbuck. *Rouen.*—1, C. A. Barnes. *Any other Distinct Breed.*—1, P. Clutterbuck. 2, Lord Ebury. 3, W. J. Loyd. *Geese.*—1 and Cup, J. Thurnham. 2 and *White.*—C. A. Barnes. 3, T. Kingsley. **TURKEYS.**—*Norfolk and Cambridge.*—1 and Champion Cup, W. Field. 2, R. Bartrum. 3, W. J. Jarvis. *Cock.*—*Price not to exceed £1 10s.*—1, W. J. Loyd. 2, C. Sneewing. 3, G. Bentley. *Ducks.*—*Price not to exceed £1 10s.*—1, T. Kingsley. *Drake.*—*Price not to exceed £1 10s.*—1, P. Clutterbuck.**

**JUDGE.**—Mr. W. Tegetmeier, Fortis Green, Finchley.

### DARLINGTON ORNITHOLOGICAL SOCIETY.

The eighth annual Exhibition of Canaries, Mules, and British and Foreign Birds (open to all England), was held in the Mechanics' Hall, Darlington, on Friday and Saturday, December 8th and 9th. The silver cup was won by J. C. Salt, Esq., of Burton, who also took a special prize as the winner of most points in classes 3, 4, 5, and 6. The other winners of special prizes were Messrs. Cleminson & Ellerton for most points in the Lizard classes; Mr. J. Thackrey, Bradford, for most points in the classes for Yorkshire birds; Messrs. Cleminson & Ellerton for most points in British Birds (17, 18, and 19); and Mr. Rutter of Sunderland, in the Belgian classes. The Show was a good one, many of the principal breeders and exhibitors competing. Besides the points being counted for the actual prizes, highly commended and commended which were liberally bestowed in most of the classes were reckoned. The general arrangements were good. The following are the prize-winners:—

**CANARIES.**—**BELGIAN.**—*Clear, Ticked, or Variegated Yellow.*—1, W. Forth. 2, J. Rutter. 3, W. Addison. *Clear, Ticked, or Variegated Buff.*—1, 2, and 3, J. Rutter. *Norwich.*—*Clear, Ticked, or Variegated Yellow.*—1, 2, and 3, J. Rutter. *White.*—*Clear, Ticked, or Variegated Buff.*—1, 2, and 3, J. Rutter. *Any other variety.*—1, 2, and 3, J. Rutter. *Even marked Yellow or Buff.*—1, J. Adams. 2, C. J. Salt. 3, Mackley Brothers. **CRESTED.**—1, W. Goodall. 2, Mackley Brothers. 3, W. & C. Barniston. Extra 3, C. J. Salt. **LIZARD.**—*Golden-spangled.*—1, Cleminson & Ellerton. 2, C. J. Salt. 3, T. Tenniswood. *Silver-spangled.*—1, T. Tenniswood. 2, S. Bunting. 3, Cleminson & Ellerton. *Gold or Silver-spangled.*

(Broken).—1 and 3 C. J. Salt. 2, T. Tenniswood. 3, S. Bunting. YORKSHIRE.—*Clear, Ticked, or Variegated Yellow*.—1, 2, and 3, J. Thackrey. *Clear, Ticked, or Variegated Buff*.—1 and 2, J. Thackrey. 3, G. Turner. CINNAMON.—*Jonque*.—1, C. J. Salt. 2, J. Adams. 3, J. Athersuch. *Buff*.—1 and 2, J. Adams. 3, Rice & Co. *GOLDFINCH MULE*.—*Any Variety except Dark*.—1 and 2, C. J. Salt. 3, J. Stevens. *Dark Jonque or Buff*.—1 and 2, C. J. Salt. 3, Mackley Brothers. *ANY OTHER VARIETY*.—1 and 2, J. Stevens. 3, J. Smeaton. *BRITISH BIRDS*.—*GOLDFINCH*.—1, W. Forth. 2, W. & C. Burniston. 3, R. Allsop; Cleminson & Ellerton. *LINNET*.—1, G. Jobling. 2 and 3, W. Carrick. 3, Cleminson & Ellerton. *ANY OTHER VARIETY*.—1, R. Humphrey. 2 and 3, J. Lacey. 3, T. Raper. *FOREIGN BIRDS*.—1, J. Scrafton. 2, R. Pearson. 3, S. Bunting. *SELLING CLASS*.—1, Brown & Gayton. 2, Cleminson & Ellerton. 3, W. Forth.

JUDGE.—Mr. G. J. Barnesby, Derby.

### CANARY TREATMENT.

IN reply to "M. S., *Sevenoaks*," respecting his Canary with a diseased beak, Mr. Barnesby says:—

The reddish-yellow swelling on the beak (the upper mandible I presume), most likely in the first instance proceeds from a cankerous and inflammatory affection of the nostrils, which in an early stage of disease might have been, and even now may be, checked with an application of lunar caustic and lard made into an ointment, in the proportions of 4 grs. of the former to about half an ounce of the latter. It is the disease alone which brings about the irritant swelling and spongy corruption upon the beak, causing it to grow unshapely. In very advanced cases recovery is hopeless. In such instances the birds are better replaced by healthy ones; but your bird being a five-year-old is no doubt a great pet, and your wish may be that "Dickey's himself again," sooner or later.

To aid the sufferer, in the first place on every other day for a week administer inwardly one drop of castor oil, and for the same period alternate the doses of oil with the above prepared ointment, each outward dressing of which consisting of a portion about the size of a small hempead, placed on the extreme base of the bill and partly on the bird's nostril. Not unfrequently a yellowish substance, the size of a hempead, will form in or about one side of the nostril, causing much pain and difficulty of breathing. With the aid of the ointment such accumulation may often be loosened and removed, inflammation stopped, and the nostril regain its proper function. Afterwards occasionally dress the bird's beak with oil of sweet almonds, applied with a small camel's-hair brush, and at any time that the spongy accumulation may appear loose gradually remove as much as you possibly can with the aid of your thumb nail, operating tenderly.

During the period of the bird partaking of castor oil give daily a little sweetened bread and milk, and at the end of about eight days continue the usual diet of seed, omitting the rape unless scalded. Mix with the seed a pinch or two of floury brimstone (sulphur), and let the bird have a piece of salt to peck at, which is an excellent blood-purifier. No lump sugar, but let the bird amuse itself with pecking at a piece of fresh carrot occasionally placed in the wires. Bird seed should always be well sieved before giving to birds. The dust, and there is a great deal in some seeds, tends to aggravate any little affection of the nostrils, encourages asthma or wheezing, and lays the foundation of diseases which often baffle those most skilled. One point bird-keepers should never lose sight of, that of giving their pets fresh water at least once a day.

In all cases of disease cleanliness is most essential; in fact, at any time, or all times, whether a bird be ill or well, and "M. S.'s" sufferer would be much benefited and outwardly purified (considering its affliction) if it could—after the foregoing treatment, say in a fortnight—be manipulated upon as follows:—Wash the bird all over, from beak to tail, with soap and warm water of the temperature of about 95°. Mind the water is not hot. Use a partly worn-out soft shaving-brush or piece of old flannel. After well rubbing either article upon a piece of common washing soap commence operating upon your bird. After five minutes rubbing and dabbing all over the bird's feathers it will be ready for rinsing in another basin of water of equal temperature, which is necessary to remove all soap from the feathers. Have at hand a clean soft linen or cambric cloth, to absorb from the feathers as much moisture as possible. Afterwards place your prostrate bird upon a cloth on the bottom of a cage, and in about twenty minutes before a fire (not too close, mind) you will see your bird upon the perch recovering from its ablution. Whilst washing the bird hold it in your clasped hand, head upwards, securely, but not to squeeze it, and do not press it too tightly around the neck, or you will frill the feathers of the same likened to a Jacobin Pigeon. I have not space here to devote in *extenso* the *modus operandi* of bird-washing, but it is simple enough, and I say Try your hand. It will cleanse your bird from some of the corruption plaguing it. Study the few remarks I have given, and if you perform clumsily at first you will do better in future. Nothing like experience. Bird-washing is necessary in other respects than for exhibition, especially when the birds are exposed to a smoky or murky atmosphere. Nothing encourages disease more than dirt, and it is necessary that not only the birds should be kept wholesome,

but also the cages they are continually penned up in. Clean perches and grit sand are two essential requisites.

### MOVEABLE VERSUS FIXED COMBS.

HAVING endeavoured to answer some of your correspondent's Mr. Pettigrew's remarks on moveable comb hives, I will now proceed to explain, as plainly as possible, for the benefit of the novice some of the advantages of moveable over fixed combs, more particularly as regards profitable honey returns, your correspondent having already ceded their superiority for scientific and experimental purposes.

Take the case of the straw competitive hive already alluded to. An imported Italian queen was placed at its head in autumn, and continuous ample feeding was resorted to, which induced great activity, and pollen was freely carried in. The last bottle food unfortunately collapsed, but the population being so numerous, were held competent to make good all damage after a clean board had been supplied. In the early summer this hive became so listless as to call for a thorough examination of its contents, when I discovered that, owing to the above accident, the masses of maturing autumnal brood had been chilled, the combs were in a damp and moulded condition, and so far as fixism was concerned its doom was sealed. A nucleus box was at once procured and stocked with four frames of empty comb, and the queen with the remaining handful of her subjects transferred, stimulated with a little feeding. Her majesty true to the prolific instinct of her race egged rapidly, one frame was removed for queen-raising elsewhere, and a full one of ripe brood given in lieu. Then an exchange of a second took place, the nucleus by-and-by becoming so crowded that its contents had to be transferred to a Stewarton breeding box shortly thereafter; that had to be nadired with a second, and the young colony thrived so well as to be independent of autumnal feeding. In short, what stood condemned by fixism became through mobilism one of the best going colonies I now possess.

Mr. Pettigrew describes we aparians as "bee-farmers," we accept the term. Farmers have their crops to reap, so have we. A good deal depends on the staff of workers, ours fortunately are all willing and industrious hands. Your correspondent prefers the old black aborigines, we go in for the Italian creoles, they are larger, bolder, we are sorry to confess much more irascible insects than their black competitors; then comes the question of the reaper, on which all farmers, bee and otherwise, are sorely exercised. Your correspondent solves the difficulty by sticking to the old straw skep, always providing it is big enough, which we may liken to the antiquated reaping hook, while we on the other hand go in for an improved implement, the Stewarton reaper. It is a self-acting machine, and has top delivery, with its several parts all moveable for transfer or repair. I will now proceed to take a look at the working of the two, beginning with the Stewarton.

By a compartmental arrangement the harvest as rapidly as reaped is sifted, the finest portions being placed together in several sectional divisions, each subdivided into seven separate parts, so thoroughly complete that it can pass from the lip of the bee to that of the consumer without being contaminated by the touch of human hand. The shallowness of the sections admit of their more rapid completion, with the consequent advantage of realising the highest price, section after section finds its way into consumption, and nearly all being disposed of before the owner of the old tool places his first sample in, possibly as in a season such as the past, an overstocked market.

The farmer possessing the Stewarton reaper with his harvest in his pocket, before going to have a look at his neighbour over the way beginning work, must first see to his machines being properly laid past for the next season. Some of his very best are clogged with an overplus, others are going light. How is the surplus to be got rid of? A whisper from Ealing Rise says, "Sling it, can't ye?" but the "weak oats" left behind the fanners we always use for feeding purposes, and mobilism again comes to our aid. We exchange overloaded for empty combs where required, no drain on the pocket for sugar feeding, not a bee is injured, or moved from its much-loved home. Here surely is the really humane system. The rich have given of their abundance, the poor have no lack; all are benefited, the vacant cells in the one case, the needful food in the other induces in both cases to the bee farmer autumnal clutches and early spring broods. So much for mobilism. I will now take a look at fixism.

Here stand the large straw skeps in much larger numbers than before, the straw hives; and despising the principle that "union is strength," permits large working parties to split up into lesser bands, and waste both their time and store in barn-building, at the very top of the season too, and in endeavours to make up the leeway all is thrown together higgledy piggedly. And now comes the real barn work, the separation of the wheat from the chaff. And how is it to be accomplished? Only by the "killing the goose for the golden egg" system—the demolition of the stocks. The very best is invariably first singled out for destruction, the farmer carefully preserves and points

out with honest pride the premier winner. Why should the bee farmer be deprived of a similar pleasure? The bees will defend their store. How are they to begot rid of? Not by the short shrift of the brimstone pit, we live in more humane times. Capital punishment is becoming rare. In return for their earnest toil the hard sentence goes forth, "That they be drummed forth the (waxen) kingdom and banished to some Siberian chilly stock, their beloved queen there slain, and they fed on sugar and water all the days of their natural lives," to obtain the requisite number of pints of that mixture known as run honey; then follows the breaking, and bruising, and squeezing, which in mercy I will draw a veil over.

Straw hives retain a place in the more shaded nooks of my apiary solely for swarming purposes, stand related to Stewartons, somewhat after the fashion Brindley put it with regard to rivers, "their use being to feed (honey) canals." On the twenty-fourth day after emergence of prime swarm, the contents of the straw hives are cut up and fitted into frames of Stewarton colonies. How helpless fixism leaves the straw hives, and to utilise his empty brood comb at the autumnal demolition of his stocks, those combs got up at such an expeditious of store and labour to his industrious workers are good for nothing but crushing up for the melting pot. The subject might be enlarged upon, but respect must be had for your valuable space.

The finest run honey such as the bee-master would like to see gracing his table is only obtainable from supers, run contents of stock boxes and breeding skeps is best utilised for bee feeding.—A RENFREWSHIRE BEE-KEEPER.

### MOVEABLE VERSUS FIXED COMB.

#### A VISIT TO THE APIARY OF THE RENFREWSHIRE BEE-KEEPER.

I HAVE just read with pleasure the interesting article from your correspondent "A RENFREWSHIRE BEE-KEEPER" on moveable versus fixed combs, and have a rather vivid recollection of a visit on the 6th of October, 1875, to his apiary, where I saw his competitive test hives, and can vouch for the lightness of the straw and solidity of the octagon hive, and I shall not readily attempt a similar trial unveiled.

Having been struck with the difference caused me all the more readily to accept an invitation to visit his apiary during the working season, which I did on the 1st of August, 1876, accompanied by a brother bee-keeper and a keen entomological friend. We were then introduced to a phase of apiculture of which we had previously no conception. Mr. Pettigrew talks of large hives: what would he think of seeing these octagon colonies towering to an altitude of close on 4 feet from their boards?—outgrown their covers, drawn back on floor boards to give abundance of alighting room, the freest egress and ingress, with ample ventilation afforded by three entrances in every case; the supers carefully covered round with woollen cloth, the several colonies shaded from the hot sunshine with archangel mats; the entire apiary stocked with Italians, pure-bred imported queens at the head of the swarming stocks, and their daughters mated with black drones at the head of the strong non-swarmers, the first-cross offspring being a large powerful insect. I need not go into a description of the purity and high finish of the fine super specimens harvested or of the glasses in process.

A source of special interest was a large mahogany rotating unicom observatory of original design. From the thermometer in the centre down to the minutest detail great ingenuity had been exercised to make it in every way practical and complete. It was stocked with pure-bred Italians, and was decidedly the finest thing of the kind we had ever seen. We watched with interest the movements of an exceedingly handsome picked queen, had pointed out to us how the workers did not object to pure air from below, keeping every perforation in zinc open, while to avoid a draught they had as carefully propolised up every crevice on the top. We traced the pollen-laden worker from the entrance to the cell, in which she deposited her load and departed for more; noted the numerous small orifices in many of the all-but-sealed honey cells, and were taught how the workers previously extracted before sealing up. There was left undisturbed a half-thickness of comb owing to its attachment to glass, affording a good opportunity of inspecting its central backbone and the sectional waxen divisions of each attenuated honey cell, with the markedly different shades of the several deposits. We could see in the outermost the honey-gatherer squirt her load, come in direct from the field; and found our Renfrewshire friend as sceptical of the "twice-swallowing and disgorging theory" as is your excellent contributor "B. & W."—putting it, in a word, that "seeing is believing."—R. J. BENNETT, Vice-President, Caledonian Apian Society.

### OUR LETTER BOX.

PIGEONS (A. L.).—Your black-and-white Pigeons seem to be Swallows.

BELGIAN CANARY (G. B. T.).—So much hempsed with sugar, particularly the latter, would tend to do your Belgian cock Canary more harm than good;

in fact, sugar is injurious to all kinds of Canaries, and we advise you to discontinue the use of it. Let a small piece of salt, fixed betwixt the wires, take the place of the sugar. Continue the hempsed sparingly during the winter months, for as the bird has been so liberally treated it would be further impaired were you to entirely take away the hempsed. Your Canary may possibly regain its musical powers after the turn of Christmas or as spring approaches, more especially if it has the company of a hen bird placed in a separate cage a short distance apart. Mix with the Canary some lettuce and cress seeds, and treat the bird occasionally with a small piece of biscuit over which half a dozen drops of sherry have been poured. In early spring some young fresh dandelion roots will benefit its health.—G. J. B.

STEWARTON HIVE (J. H. Ebridge).—"RENFREWSHIRE BEE-KEEPER" writes:—"Mr. James Allan, cabinet-maker, Stewarton, Ayrshire, makes my hives, and will doubtless furnish estimate cost and carriage on application. The Stewarton breeding and honey boxes measure 14 by 14 inches, and are 7 inches deep for former and 4 for latter. For a beginner two 9-inch-deep boxes might do well for stocks' breeding space. Like all light-wooded hives they must have external protection. Mine stand in octagon covers 18 by 18 inches inside measure, body and top both moveable, the latter covered with thin zinc, with ornamental vase on the top, and well painted stone colour. These rest on mahogany boards made from old dining-table tops. Woodbury hives are of square form, and having crown boards are not well adapted for storing in the Stewarton. Communication can be given or shut off by means of the slides without disturbing the boxes. My bees have a little heather honey from some hills half to a mile distant. Independence of spring feeding is due to the weight of surplus store left in autumn of such strong non-swarming colonies."

### REMARKS.

- 6th.—Fine morning and pleasant day, though sometimes rather cloudy.  
 7th.—Rainy morning, and showers at times all day, sometimes heavy ones.  
 8th.—Fair but rather dark morning; rain before 10 A.M., and showery all the rest of the day.  
 9th.—Slight frost in the morning; a fine pleasant day, rather less so at night.  
 10th.—Fair but hazy early, and rather dull all day.  
 11th.—Very foggy, dull, and dark all the fore part of the day, and slight rain towards night.  
 12th.—Fair but hazy and dark early, better before 10 A.M.; rain commenced before 11, slightly at first, but all the remainder of the day was rainy; but fine at night.  
 A gloomy week, and somewhat colder than the previous one.—G. J. SYMONS.

### COVENT GARDEN MARKET.—DECEMBER 13.

BUSINESS remains quiet in both fruit and vegetables, and trade is restricted owing to the almost continuous wet weather which has lately prevailed.

From observations taken near London during forty-three years, the average day temperature of the week is 41.2°; and its night temperature 31.4°.

## GARDEN IVIES, THEIR USES AND CULTIVATION.

**G**ARDEN Ivies are more useful than the little attention paid to them would lead any one to suppose. The number of their varieties would vie with many of our florists' flowers, and I think a good collection of Ivies to be no small addition to any garden.

"A rare old plant is the Ivy green," says Dickens, and such indeed it is; for many are the fine old ruins and buildings that we see covered with its verdant foliage always pleasing and attractive. The chief characteristic of Ivy is that of a climber, although it may be grown in a variety of other ways, which I shall endeavour to notice, affording also some hints relative to its cultivation and management under its different forms of growth.

Ivy will climb as long as it has anything to adhere to, but when it has reached the summit of its support and has nothing to cling to its nature changes; it ceases to emit aerial roots or clingers, and throws out horizontal branches which terminate in flowers and fruit. The time of flowering is September and October, and the berries ripen in early spring, when they look very beautiful as they hang in black clusters. One characteristic of the Ivy is this: If growing up a wall or old building and its main stem becomes severed from the ground it will still live by reason of its aerial roots adhering firmly and feeding on the substance to which they cling; but if growing up a living tree and it becomes severed from the ground it may live for a time, but will not thrive if compelled to derive support from the bark of the tree alone. I believe Ivy to be hurtful to trees, for when once it obtains the mastery over them it checks the flow of sap in the bark, deprives the trunk of light and air, and decay of the tree is the result. The trees it seems to favour most are the Oak and the Elm. In the grounds of Wimbledon House there is a fine old pollard Oak grandly covered with Ivy; with the exception of a small branch the Oak is quite dead, having become completely smothered by this evergreen marauder.

Some people affirm that Ivy is hurtful to buildings; such may be the case where in the course of years its aerial roots have penetrated the brickwork and loosened it. For instance, I recently saw an account that the walls of Arundel Castle were threatened with destruction through the fissures in them caused by this means; the evil was checked and the masonry preserved by pulling the Ivy down. Generally, however, it is a protection to a building by excluding wet, and it also holds many a ruin together.

The uses of the Ivy are many—namely, protection to buildings, food for cattle; the flowers being rich in honey provide food also for bees and numberless insects, and the berries are food for birds. In the garden it is employed as coverings for walls, for decorating the flower garden and conservatory during winter, as edgings for beds, carpetings under trees, and especially for embel-

lishing churches and rooms at Christmas-tide. If grown in pots and plunged in beds with a piece of crock under the pots to keep out the worms specimen Ivies look well in the flower garden during winter when mixed with a few Yews and Hollies. When many shrubs are bare and leafless I think such specimens are a great means of cheering the dreary aspect of the winter months.

The Ivy may be propagated by seeds, cuttings, layers, and grafting. When the seeds are ripe they may be gathered and sown thickly in a bed of sandy soil. Keep the ground clear of weeds. When the seedlings are of sufficient size plant them in rows in a nursery bed, and after they are strong enough plant them where required for permanent use or effect. Variegated kinds are rarely raised from seed, but are sports from the green varieties. The sports may be propagated by taking off a young shoot 4 inches long, with some green in the leaf, and inserting under hand-glasses in sandy soil.

Cuttings may be quickly struck by taking young shoots from a wall, and inserting them in pots or in the ground; they seldom fail to root if put in in June or July. Layers may be obtained by pegging-down long shoots on any damp soil; they root quickly in old cocoa-nut refuse, and may be multiplied to any extent. Or another way is, in July procure long cuttings, and instead of putting them upright in the pots peg them down firmly; these will root at each joint, and as many plants can be made as desirable. Grafting is performed in nurseries, therefore I shall not say anything on that mode of increase.

The Ivy will grow in any soil, good garden ground suiting it very well when planted out; but for growing in pots it requires good loam, manure, and leaf soil, especially if it is to remain in the pots for a great length of time. The large-leaved green and free-growing varieties thrive in a moist soil, but the variegated kinds require a poorer soil, so as to retain their rich colours, otherwise they will be liable to revert to their normal colour—green.

If good variegated specimens are required the soil suitable for them is a light loam mixed with old broken brick rubbish. They should in all respects be treated as hardy plants and be given every exposure to the weather. Different aspects exert considerable influence on colour; dark rich shades are obtained by exposure on a damp north wall, while the lighter-coloured blotches are clearer when fully exposed to light; but in all cases shelter and shade promote free growth and bring out rich green hues.

The best Ivies for walls are the quick-growing large-leaved sorts—namely, *Hedera canariensis*, *H. algeriensis*, *H. Roegneriana*, and *H. dentata*. The common English Ivy (*Hedera Helix*) looks neat and clings closely, but is a slower grower than those that I have named. The variegated kinds look well on walls also. When Ivy is to be planted for covering a wall strong plants should be obtained, and planted in April in deeply-dug ground, watering the plants and nailing the shoots until they attach themselves to the masonry, when they will require no further attention beyond securing stray loose shoots. When thoroughly established all the leaves and lateral

may be cut back close to the stems annually in March or April, when young leaves will speedily be produced and have a neat and pleasing appearance all the season.

Ivy may be grown as standards, bushes, pyramids, and "umbrellas." The vigorous green-leaved kinds make good standards. Strike the cuttings in pots in July or August, and keep them in a cold frame during winter. In April pick out those with straight leaders and plant them out in well-manured soil, keep them trained to stakes, and in July pinch the side shoots in to two or three leaves; the next season cut the leader back to the height required for the standard, preserve the side growths for forming the head, and train them out so as to keep vigour in them, but pinch the side shoots so as to prevent them taking the lead and depriving the head of support; the next season cut the leaders back to three buds. By following this treatment for about four years good specimens will be established ready to be planted for ornamentation on lawns or in shrubbery borders. After so planted out remove the side shoots from the stem a few at a time, commencing at the bottom, when clean stems will be produced, and the heads can be trained to any shape required, or be left to flower and fruit in their own wild way.

Pyramids are easily formed by inserting a few stakes in the pots, and taking the side shoots round the stakes, which will soon be furnished, and in the autumn, after growth is finished, tying the stakes firmly together at the top. If the plants have been kept growing freely they will be of good size to be effective the second year, and may be kept in the same pots for several years, provided the soil is good loam and manure. During the summer plunge the pots in old leaves or cocoa-nut refuse, and keep the plants well watered. Plants so treated make good specimens either for flower beds, conservatories, corridors, or rooms during the winter months. "Umbrellas" may be formed by taking a shoot straight up and training it out on a head of wirework until the outline is covered, then pinching the side shoots so as to form the head into a dense mass of foliage. The side shoots must afterwards be removed from the stem, as previously stated. This style is useful for various purposes of decoration.

Bushes can be grown in pots of either the climbing or fruiting varieties. I have seen the yellow-berried variety (*H. chrysocarpa*) look beautiful in winter with its bright berries and green foliage. It takes time to grow good bush specimens. In all respects they require the same treatment as the others, and should not be pruned unless a strong shoot push out beyond the rest. All fruiting varieties are well adapted for bushes, as they require no training, and are useful in the flower garden during winter.

The following are some of the varieties I am acquainted with, and they consist of the largest and smallest leaved kinds in cultivation—namely, *H. canariensis*, *H. algeriensis*, *H. dentata*, *H. Rœgnieriana*, *H. digitata*, *H. digitata nova*, *H. chrysocarpa*, *H. Dondrierensis* (minima), *H. maculata*, *H. elegantissima*, *H. sagittifolia*, *H. taurica*, *H. Caenwoodiana*, *H. palmata*, *H. chrysophylla*, and *H. elegantissima marginata*.—ALFRED ALDERMAN.—(Read before the Wimbledon Gardeners' Improvement Society.)

## A GARDEN OF HARDY FLOWERS.—No. 4.

### PLANTS WITH A HISTORY.

How to plant a garden to ensure a maximum of pleasure with a minimum of future trouble. This was the gist of "IGNORAMUS'S" appeal, and I am trying to show how it may be done; but in doing so I must be careful not to mislead my amateur friends. Gardens are perhaps especially subject to the mutation of time, and the "once for all" system is applicable to very few gardening operations. It is true that much labour and expense may be avoided by planting hardy flowers; but weeds will grow, the flowers become crowded, blossom and foliage perish and become unsightly, "change and decay" are ever going on, and therefore for a garden of any kind to be kept in good order a constant and daily supervision must be maintained, except perhaps just in midwinter.

Now, do not turn away with the idea that if you follow me there will be nothing for it but to have professional assistance during the greater part of the year, for I certainly do not mean to advise such a course. If the owners of small gardens wish to derive much pleasure from them, hired help, except for the more laborious work, must be dispensed with. Spend part of every day in your garden, even if it be but a brief hour. Procure as many of the plants as you can yourself, plant them

with your own hands, and cherish them. Avail yourself of every trip or tour countrywards to enrich your store, and your garden will constantly grow in interest as well as in beauty; in interest especially, because its occupants—the offspring of your own exertions, either by propagation or collection—will possess a charm altogether distinct and superior to that of plants planted or cultivated by hiring hands. They will speak to you in a language understood by you alone, recalling to memory many a bright hour of your life, incidents of travel, cherished acts of friendship, scenes that you have visited "long, long ago." Do my readers yet understand what is meant by "plants with a history?" Do they recognise the fact that by devoting a little of their own superfluous energy to their gardens they may not only have the enjoyment of healthy recreation—invaluable at the moment, but secure a fund of future enjoyment, from which they may draw largely without any risk of exhausting the source of pleasure so pure, and so unselfish withal? "I found that Parsley Fern on a mountain in Westmoreland." "These tufts of Saxifraga we brought from the ruins of a Pictish fort in the Isle of Skye." "That *Silene maritima* was pulled off some rocks at Torquay by J——." "I brought those Maidenhair Ferns and the *Coronilla* from Lecce, and we found these *Cyclamens* on Monte Campione." Such are a few of the remarks one hears made of "plants with a history," often followed by anecdotes—incidents of the road or descriptions of scenery.

Many such anecdotes could I repeat were my object simply to amuse. One of them is worthy of a place here as serving to enforce my teaching. Walking round a garden a short time ago, which was literally crowded with "plants with a history," I paused to examine a curious and uncommon form of the familiar Heart's-tongue Fern. The plant was a fine one, and had a special corner devoted exclusively to it. "Ah!" said its owner, "that is a great treasure, and I got it in a curious manner. I was shooting in Ireland, and shot a snipe which fell right into this Fern. I saw at a glance that it was a rarity, managed to pull it up, and went off with the snipe in one pocket and the Fern in another." There, "IGNORAMUS," that is the spirit with which real lovers of a garden are imbued. Cultivate it, and you will find that life has one more pleasure worthy of the name, that gardening is not so very difficult when you throw your heart into the work, and that a garden tended in the manner in which I am trying to aid you to tend yours is about the nearest approach to the "philosopher's stone" that has been or it is likely will be discovered. In the garden you will always find food for the mind as well as for the body. Cherish, then, your garden, and it will become a veritable treasure-house of "rich memories," suggestive of kindly thoughts and noble aspirations.

Christmas-tide is near. Many gardens will aid in making it joyous, and that many more may have a similar result before the close of the "next new year" is the "Christmas greeting" of—EDWARD LUCKHURST.

## GRAPE VINE MILDEW.

ON account of a pretty general prevalence of mildew on Vines during the past season the various popular remedies have obtained a considerable amount of attention, and more than usual has been written about them. I have attended to the culture of the Vine for about eighteen years, and never saw mildew on my Vines until the past summer, and as my treatment of it was a complete success I gladly avail myself of your pages to make it known.

In July the pest made its appearance in a span-roofed house 80 feet long, planted principally with Lady Downe's. The Vines first attacked, however, were two Muscat Hamburghs, but the disease spread with considerable rapidity throughout the house. Sulphur was recommended to me as the only antidote, which I applied to the hot-water pipes in a liquid state, and as a powder to the bunches and foliage most affected. I continued these applications for four or five weeks without making any appreciable improvement in the condition of the Vines.

By this time I had begun to fear that the whole crop would be sacrificed or at least materially injured, when I had a remedy brought under my notice which had been successfully tried by Mr. Harrison, of Darlington, for Roses. It is advertised as "Silk Cocoon Liquid Manure," and is from the silk mills of Messrs. Lister & Co., Manningham near Bradford, and was sold at that time by their agent, Mr. John Harrison of Whash-ton near Richmond in Yorkshire, who is now dead, but I believe

the agency is still held by his widow. I resolved to try it, and on one application cleared the house of the pest without injury to the fruit, which had already commenced colouring. I may state that the seedling bunch of Grapes which was awarded a first-class certificate by the Royal Horticultural Society on the 6th was one of the bunches so operated on, and what I look upon as remarkable is that in a very few days after the liquid was applied the Vines began to assume a fine healthy appearance, which continued during the whole of the season.

In a Hamburgh house 40 feet long the disease made its appearance as the fruit was ripening, and I decided not to apply the "cocoon liquid" until the fruit was cut, by which time the disease had spread very generally throughout the house, but I found that one application was quite as effectual in removing it as in the former case. I intend using it also as a winter dressing for the Vines, and believe it will prove a most valuable preventive as well as cure for mildew.—D. P. BELL.

#### CULTURE OF POINSETTIA PULCHERRIMA.

This plant is now very extensively cultivated, and well it deserves to be, as there are few subjects more showy and better adapted for decorative purposes at this season of the year. The system of culture I have adopted is different from that of many cultivators, but as I have been successful with it for many years, I thought a few remarks on culture would be useful.

The plant is a native of Mexico, having been discovered in that country by Mr. Poinsett in 1828, and whether different varieties of the species were sent over, or whether the difference in cultivation has the effect of improving the quality of the floral bracts I know not, but I have certainly not seen better or more brilliant specimens anywhere than have been produced by the culture here described.

When the flowering period is over the plants are gradually dried off, and the pots laid on their sides underneath the stage in a cool stove, where they remain until the end of March. In that month the young growths of last season are cut down to within three or four eyes from the base of the growth. No water is applied to the roots until the wounds are dried up, but the pots are removed to the greenhouse, where they are placed on the stage near the glass, and there they remain, water being applied to the roots when it is required, but no more than is necessary to maintain a healthy growth. They do not require nearly so much water here as they would in the plant stove, where the heat would be 55° or 60° at night. When the buds have started about half an inch the plants must be turned out of the pots and repotted; and to grow this plant well it requires a rich compost. The following answers admirably: rich turfy loam five parts, one part decayed stable manure, one part leaf soil, and an 8-inch potful of crushed bones to each barrowload of the compost; a little sand is necessary if the loam is of a close texture. Drain the pots well, and place over the broken potsherds some of the fibrous part of the loam from which the clayey particles have been well shaken out; if the finer portion of the compost becomes mixed with the drainage the plants will not retain their leaves to the end of the season. After potting, the plants should be kept near the glass and be fully exposed to sunshine, and the house be freely aired; this will cause the growths to come strong and short-jointed, the leaves to be thick and leathery, and the wood will be of a reddish tint. When the pots are filled with roots, which will be by the middle of May, the plants may be repotted in similar compost to the above, and by the middle of June they may be removed to a position out of doors where they are partially shaded from the sun. I have found they do best on the north or west side of a low house where the tops of the plants are exposed to the sun and the lower portion sheltered from its rays. If they are exposed to the direct force of a strong gale of wind many of the leaves are injured. In this position they must not at any time suffer by want of water at the roots, as this would also cause some of the leaves to drop off, and the object of the cultivator is to see that this does not occur, as the loss of the lower or any leaves very much impairs the beauty of the plants.

About the middle of September we remove the plants to a house where there is a night temperature of 50° or 55°, and this ought not to be exceeded until the floral bracts begin forming, when the night temperature should be 65° until they are fully developed. I ought to mention that as soon as the plants are taken indoors they may be well watered with manure water; every alternate watering may be of guano water. This

deepens the green of the stem and leaves, and adds brilliancy to the floral bracts.

Propagation is effected by cutting the stem into short lengths and inserting the eyes in the same way as Vine eyes; they thus grow as freely as Vines, requiring very similar treatment. Another method equally simple is this: When the young growths are 3 or 4 inches in length it will often be found that there are more on the plants than ought to be allowed to remain. Let the surplus growths be taken off with heels and be placed in a gentle bottom heat under a bell-glass, where they will, if shaded from the sun, very soon strike out roots. If each cutting is potted in sandy loam in a thumb pot the plants will not suffer anything when they are repotted. In three weeks from the time of putting in the cuttings the plants will be ready to be repotted. After being established they may gradually be inured to a cooler atmosphere, and be ultimately placed out of doors and be treated as has been recommended for the established plants.

The Poinsettia does not require very much pot room; the summer-struck cuttings may be placed in pots 4 inches in diameter, or three may be potted in 6-inch pots. We have some in 6-inch pots from cuttings struck in June; each pot contains three plants, which stand 15 inches from the surface of the pots, and the floral bracts are as much as 15 inches across.

There are several varieties, some of them from seeds ripened in this country. The Messrs. Veitch of Chelsea exhibited a distinct form at the December Committee meeting at South Kensington, and the same enterprising firm have this year introduced the marvellous and distinct variety *P. pulcherrima plenissima*. I have grown this variety during the present season, but the plants were not obtained until it was too late to put them under the above system of cultivation, and they were not placed out of doors at all. This variety seems to be later than the old sort, and the bracts take a much longer time to develop themselves; so that I shall not be able to report fully on this variety for at least six weeks, for it will be that time before our earliest specimen has attained to its full development.—J. DOUGLAS.

[We have seen Poinsettias which have been grown by Mr. Douglas, and have noted their superiority.—EDS.]

#### THE RUSSIAN TRANSPARENT APPLE.

UNDER the heading of "Greasy Coat" Apple a discussion was lately conducted in this Journal, and the Transparent Codlin was then noticed as possibly being the variety referred to by "J. J., Lancashire." In that discussion I mentioned the "Transparent" as having (in common with many others) a greasy skin, but I more particularly noticed it as being a valuable Apple—a certain bearer, and the tree a "rent-paying tree" when grown in cottage gardens. I had the best proof for that estimate, for I was intimately connected with a fine standard tree which for a great number of years unfailingly contributed materially in defraying the rent of the garden in which it grew. I have since learned something of the history of this valuable Apple. A farmer in Lincolnshire (Mr. Beulah), who has a great knowledge of hardy fruits, and cultivates a large number of new and old varieties, has favoured me with information which he has special reason to consider as being perfectly trustworthy and reliable.

In the first place Mr. Beulah thinks that the "Transparent" which I referred to on page 298 (and of which he and myself both think so highly), is not in commerce further than possibly having a place in a few small local nurseries in the district of its introduction. The history of this Apple is as follows:—

During the occupation of the district around Moscow by the invading army of the first Napoleon General Boucherett, the representative of an old Lincolnshire family still existing in the county, noticed this Apple growing freely in Russia, and being attracted by its fine appearance and presumptive hardiness, considered that it would be a valuable variety for English gardens. A large number of grafts were therefore brought by the General to Lincolnshire, and thus the Russian Transparent obtained a footing on our shores, and has proved in the locality of its introduction one of the most profitable of our fruits. Mr. Beulah's authority for this statement is that one of his relatives was in the suite of the General, and has left it on record that he had a distinct recollection of the facts referred to, and of the arrival of the "faggot" of grafts at Willingham House.

The spread of this Apple in north Lincolnshire is attribut-

able, in Mr. Beaulah's opinion, to a local nurseryman, a late Mr. Brown of Barton-on-Humber. Mr. Brown has been dead many years, but his name is still remembered and his fame is still existent as a man who had a great knowledge of fruits, and distributed more good varieties in north Lincolnshire than any other grower. In all probability Mr. Brown on seeing the Russian Apple recognised its value, procured grafts of it, and eventually added it to his small but good collection of Apples. Mr. Brown's catalogues are still extant. The list of Apples numbers only sixteen, and the Russian Transparent is therein included.

I have visited many gardens and nurseries in many counties, but have never seen this Apple except in north Lincolnshire. I have seen many trees of it there, but I cannot remember the fine specimen which I have so many scores of times climbed and robbed ever failing to supply a valuable crop of fruit. Mr. Beaulah finds the Transparent equally constant now, and one of the best, if not the most profitable, of all the sorts in his well-chosen collection. The inclement weather of the past spring destroyed the blossom of all the Apples in his garden except this and the Cockpit, and he has for some time past been selling his Russian Transparents readily at 3s. per stone of 14 lbs.

The tree forms a noble head and produces pendulous branches. Its blossom is very large, white, and handsome, and does not open—and this constitutes its great value—for fully a week after the average period of blossoming of other varieties. Dr. Hogg has examined specimens of the fruit, and has favoured me with the following description:—"Fruit large, roundish, somewhat oblate, narrowing towards the crown, where it terminates in several prominent ridges, occasioned by the rather prominent angles on the sides, flat at the base. Skin smooth and shining, grass green, becoming yellowish green as it ripens, strewed with large russet dots, and containing a few pearly specks. Eye closed, with connivent segments, set in a narrow and puckered or angular basin; stamens median; tube short funnel-shaped; seat of the styles conical, broad at the base; cells of the core closed. Stalk medium, inserted in a very wide funnel-shaped cavity. Flesh very tender and juicy, with a pleasant subacid flavour, and a peculiar and agreeable aroma." I am convinced that this is one of the most valuable culinary Apples in cultivation, and is worthy of more than local fame."

If I have omitted any particulars respecting it which are worthy of being known, perhaps Mr. Beaulah, who is a Journal reader, will favour by supplying them. "J. J. Lancashire," will also oblige by sending to me his name and address through the Editors of the *Journal of Horticulture*.—J., Lincolnshire.

### PREPARING POTATOES FOR PLANTING.

No practice in Potato culture is more important than a careful preparation of the sets. At first sight this may not be regarded as a cultural point, but in reality it is one of considerable moment. It should be remembered that the Potato may be cultivated when it is out of the soil as advantageously as when growing in it. If a plot of ground is planted with Potatoes, and the crop is left untended and becomes choked with weeds, we do not call that crop cultivated, but neglected. Similarly when Potatoes which are intended for planting are heedlessly left in heaps to be choked with their own growth they are also neglected; but if their growth is conserved and assisted from the earliest stages onward, that attention must rightly be regarded as cultivation, for it adds considerably to the yield and value of the crops.

In order to have the best results in Potato-growing cultivation must commence several weeks, even months, before the sets are planted in the garden. In many gardens only early Potatoes are grown, the main crops being provided by field culture. It is to garden Potatoes, therefore, to which I am now alluding, limiting my remarks to the earliest sorts—sorts which have a post of honour in being grown on the cherished "south border." The ground space on this border is necessarily limited, and every crop is consequently desired to be in the fullest manner productive, including the crop of Potatoes, which is one of the most important crops of the season.

Advice is occasionally given as to the best time for planting Potatoes, also as to the size of tubers best for sets and the manure which is the most suitable for the crop. That advice may be, and has been, good in itself, but I assert with that confidence which is warranted by experience that neither the time of planting, size of sets, nor choice of manure is so im-

portant as the preparation of the tubers—in other words, the cultivation of the Potato when out of the ground.

That cultivation must begin now. Not one more day's delay should willingly be permitted. The growth of early Potatoes has already commenced; do not neglect that growth, but assist it—cultivate it. If the tubers are covered with straw and soil—graved—young growth will now be active, for the weather is mild, and for some time the temperature has been high for the season of the year. Open the "graves" and remove the tubers required for planting, and place them thinly in a light position, so that their growth may be conserved and directed to a good purpose instead of being wasted in the dark regions of the "grave." If the tubers have been stored in boxes or hampers, placed in dark sheds, empty them at once and place the tubers thinly in a place where they can have light. Even if they are placed thinly in a dark place their growth will not be useful growth; it will be white and wiry, and more likely than not to be broken or injured when placed in the soil.

It should be remembered that Potatoes will produce growths of greater length in a dark place, even it is cool, than they will in a light place if it is warm, but the growth produced under the influence of light is a certain gain to the future crop, while that produced in darkness is a certain loss if the growth proceeds far. The growth of a Potato in a light place is stout and firm and cannot be injured or knocked off by any fair or ordinary means, but the growth produced in a dark place is liable to destruction, either by removal of the tubers before planting or by the pressure of the soil after they have been planted.

If anyone desires to note the advantage of careful preparation of the sets before planting them, let him take half a dozen tubers which have made their growth under the influence of light. The growth on each set should be half an inch in length, green, and stout as the tip of one's little finger. It will adhere to the tuber firmly, so firmly that it cannot be severed from it without considerable force; the growth will also be studded with rootlets at its base, and which will rest firmly on the parent tuber. Let him also take another half-dozen tubers which have not been prepared, but which have produced as best they could a cluster of white thin appendages which are broken with the slightest touch. Let him plant these two half-dozen in pots, and place them in a frame or house for the purpose of producing an early crop. He will find that the produce from the prepared tubers will be of double the value of that of the unprepared tubers, and the former will also be ready for use much sooner than the latter. The advantages of preparing the sets is equally striking in outdoor cultivation, and one peck of tubers well prepared will give a better return than will two pecks the tubers of which have received no care previous to planting them; the gain thus resulting from careful and good cultivation out of the ground is effected by a direct and important saving of land, manure, labour, and seed tubers. That is not deducible by logic merely, or is a "pretty theory looking well on paper," but is the result of careful experiment and practice, as plain and actual as even the practical Mr. W. Taylor could desire. Indeed, I should not be surprised if that cultivator has not himself proved it.

I will now go a step further, and assert without any reservation that tubers not much larger than walnuts will, if properly prepared, produce a better yield than will other tubers of three times the size which have received no preparation. I am warranted even in going further than that, for I have proved conclusively that if a good-sized tuber is cut in halves and both are well prepared, that either of the halves will produce a better return than will one large whole tuber that has received no attention in preserving and assisting its early growth when out of the ground.

All Potatoes intended for producing the earliest crops out of doors should now be placed closely together, with their growing ends upwards in a light position, and in a place more or less warm according to the backwardness of the growth and of the amount of light to which the sets are exposed. In a very light place the tubers push growth slowly, even if the temperature is high, while in a semi-dark place they grow rapidly in a moderate temperature. When thus placed the tubers take up but little room, and those who have not adopted the plan will be surprised how small is the surface occupied by a peck of kidney-shaped Potatoes when closely packed on their ends. By thus packing them only the main eyes will elongate, the side eyes remaining nearly dormant, and thus very vigorous stems are provided which are essential for producing a perfect crop. If only a very few tubers are required in the best condi-

tion they should be packed in leaf soil and be kept moist by syringing them occasionally, yet they grow quite freely without any soil.

It is most important that Potatoes for planting should be carefully prepared, for if neglected in the early stages of their growth when out of the ground, no after care, no mode of planting, no sort of soil, and no additions of manure can compensate for the neglect, and can produce the best possible crop at the earliest possible period.—A NORTHERN GARDENER.

### BUPLEURUM FRUTICOSUM.

THIS is said to have been introduced to this country about 1596. From that time to the present one would have thought that it would have been met with almost everywhere, but it appears to have found little favour in public estimation: perhaps it is

Fig. 76.—*Bupleurum fruticosum*.

little known. It is a charming umbelliferous dwarf evergreen shrub, having fine glaucous shining foliage, which makes it very desirable in a choice selection of flowering shrubs, and its umbels of pretty yellow flowers give a charm to it during the summer months. It is worthy of a place in shrubbery borders, being of dwarf habit, and with a little care may be made an object of great beauty. It requires an open and moderately dry situation. It may be increased by cuttings of half-ripened shoots inserted in well-drained pots filled with very sandy soil, plunging the pots in sand or ashes in a cold pit or frame. This shrub might possibly be turned to good account for indoor decorative purposes.—N.

### CARROT GROWING.

I, LAST winter, trenched a small piece of ground where formerly nothing but rushes were produced. Throughout the early part of the year it was frequently stirred up and broken with a five-tined fork, at the same time mixing in a good quantity of soot, guano and sand. I added the sand to make the soil work better, it being a wet spongy peat. In April the seed was sown, and I must say that I have never seen a better crop of Carrots.

I write this to show that Carrots can be grown on what I may term waste land, where scarcely anything else will succeed. In this country (Dumfries-shire), there are thousands of acres of waste land, which if cultivated would yield magnificent crops of this useful esculent, at the least worth £40 or £50 per acre. I should say that an acre of Carrots similar to those I lifted a few days since would in the market be worth £70.—JAMES DICKSON.

### THE ROSE CONFERENCE.

THE queen of flowers has for so long a time been a speciality of the Journal, that it was natural that our "most potent, grave, and reverend seigneurs" should have desired to give its readers a report of a meeting which some of us believe to be the most important one that has ever been held in connection with our cherished flower, and I am sure we all feel indebted to them for the full account that was given of it in last week's number. I know under what difficulties the reporter laboured, and I only wonder how he could have managed to be so full and generally accurate; but as in a meeting like that, where there are many speakers, there is always a difficulty in ascertaining the exact details, and I have only to refer to a few corrections. The first resolution that was passed was "That a National Rose Society be formed." There was no society to revive, as none had ever existed, although some confusion existed in the minds of some present on this point. The second resolution was "That the first Show be held in St. James's Hall on either July 4th or June 28th," not July 1st, which falls next year on a Sunday, and at which we parsons at any rate should rebel. But this was clearly a slip of the pen. It was found afterwards that the Hall could not be had for June 28th, so it was engaged for July 4th, with the understanding that if a show be held in London in 1878 it should be on the last Thursday in June; the date for 1877 suiting the more northern and midland growers, while that for 1878 would be more agreeable to the southerners.

Mr. Cant's question with regard to Mr. Mayor was a natural one; but there were many present who know him not only to be a keen rosarian and an ardent horticulturist, but a thorough man of business of kind and conciliatory manners. Without his aid I could not have undertaken the post which the meeting wished me to do. He will be financial Secretary, for, like most parsons, I am a shocking bad hand at figures, and moreover the Horticultural Club gives me quite as much of that as I care for. It was a mistake to represent me as saying that Mr. Mayor resided in my neighbourhood, for he lives at Winchmore Hill. What I did say was that we were members of the Club, and so had often opportunities of meeting. I have already seen what a valuable helpmate he will be, and I think if the success of the movement depends on the Secretaries pulling together, our friends need be under no apprehensions.

Many thanks, my dear "WILD SAVAGE," for the kindly way in which you have written of poor wooden "D." It was in truth a meeting of which I felt not a little proud. How worthily was the Rose represented! It was pleasant to see the worthy son of the father of Rose-growing in England there, for I think all will accord this to Thomas Rivers, whose indefatigable industry and skill have more than anything tended to make English Rose-growing what it is; to see the heads of the two sister firms of Cheshunt and Waltham Cross; the Colchester hero, too, with all his blushing honours of the past season thick upon him; the hearty and genial champion of the Manetti from Hereford; the king of florists from Slough; the prince of the seedling Briar from Oxford; and the goodly company of amateurs from all parts. And as after dinner we sat discussing the merits of the various Roses, one might have thought we were met together on a sunny day in June rather than on the dreariest of winter days.

And may I not add, too, that it proved the value and usefulness of the Horticultural Club as a central rallying point for all who love the craft? Here at once was a place for the meeting, so central that in two minutes you are in the busiest part of the Strand, and yet so quiet that all the traffic through that busy thoroughfare was as absolutely unheard as if we had been miles away, while the offer of the use of the rooms for the Committee of the National Rose Society at once relieved them of any trouble on the score of expense or a place of meeting.

The letters which I held in my hand represented a larger number of supporters than those present, and one and all

expressed a hearty concurrence in the movement. There was one whose absence all who knew him could not refrain from deploring, one well known to the readers of our Journal—my excellent and genial friend C. P. Peach; a regret increased by the knowledge that it was occasioned through severe illness, an illness contracted in the indefatigable discharge of his clerical duties, and from which he is slowly recovering.

Again I would express my sincere thanks to all who so kindly responded to my invitation, and earnestly hope that everything connected with our new Society may be indeed *couleur de Rose*.—D., Deal.

### CHOICE CLIMBING PLANTS FOR INDOOR DECORATION.

MANY plants of climbing habits are now used for the decoration of pillars, walls, and rafters of stoves and conservatories. Some climbing plants require an exotic heat to grow them well, and others succeed best when grown in a cool atmosphere; in fact there are no scarcity of choice plants of both classes, and a careful selection from both will add beauty and interest to all kinds of plant structures. Some plants have sweet-scented flowers, others have showy leaves without flowers of any importance; but with the great demand for cut flowers which now exists in nearly every garden climbing plants that will supply plenty of flowers suitable for cutting are those most in demand, and which deserve to be grown most extensively.

Amongst stove climbers the old *Stephanotis floribunda* is well known to be of great value. Its green leaves have no special attractions, but its flowers are unsurpassed in their purity of colour and fragrance. Cutting them does not disfigure the appearance of the plant, and there is no kind of floral arrangement into which the flowers cannot be wrought with advantage. The *Stephanotis* is very common, yet I do not think it is so much grown as it should be for cutting from. Instead of growing only perhaps a single plant of it up a rafter, it should be planted in every odd corner of a heated structure where space can be afforded.

The worst feature of the plant is its filthy nature. There is no plant in our gardens to which mealy bug and other insects are more attached. Still, when these are not allowed to make much headway it is surprising how little attention the plants require in the way of being kept clean. Frequent sponging is the best way of cleansing, and syringing often has a tendency to accomplish the same end.

Allamandas are useful hothouse climbers so long as the flowers are only wanted on the plants, but I have never found them in much demand in a cut state. All the flowers are yellow and rather clumsy in form, but they are generally produced in great numbers, and are very showy on the roof of a stove. A. Shottii does not produce such large flowers as A. Hendersonii, which is the variety most to be preferred.

Dipladenias might be classed with Allamandas so far as the form and general character of the flowers is concerned, but the former are much more attractive than the latter—indeed the Dipladenias are the finest flowering stove climbers we possess. I have no doubt the old rosy-crimson-flowering D. *amabilis* will be the best known to many readers; and although it is not so brilliant as the newer D. *Brearilyana*, it is still to be preferred as being freer in growth and more likely to succeed with those not accustomed to deal with shy-growing plants.

Were I restricted to one stove climber besides the *Stephanotis* I would have no hesitation in selecting *Clerodendron Balfourii*. Its lovely crimson and white flowers are not only highly ornamental on the plant, but in a cut state they are exceedingly useful, and as they are always produced in abundance the value of the plant is thereby much increased.

These four distinct stove climbers may all be grown to perfection under the same circumstances. The plants are often grown in pots and trained round small trellises, but their attractions are never seen to the greatest advantage under this restricted system of growth. To develop their beauty to the fullest extent every one of them should be planted out and allowed plenty of room for extension and development. A mixture of loam, peat, and sand suits them well, and good drainage and liberal cultivation in every way I always find to be most remunerative.

*Hoya carnosa* is a quick-growing plant, which does better in a warm stove than in a cool greenhouse. It delights in plenty of peat and sand. The flowers are produced in clusters, are pinkish-white in colour, and of a waxy texture. They are admirably suited for bouquets and button-holes.

*Ipomoea Horsfalliae* is another choice climber which should find a place in every stove. The flowers are produced freely in autumn, and are of a bright crimson colour. It does very well on a shaded back wall where many other plants will not grow.

The best of the *Passifloras* for general purposes I consider to be *P. alata*, *P. amabilis*, *P. fulgens*, and *P. quadrangularis*, all the flowers of which are very attractive, and the fruit of the last-named is of considerable merit for dessert. Like other climbers they do best planted out, and a little decayed manure may be added to the loam and peat in which they are placed.

Those selecting greenhouse climbers must never think of leaving out the two *Lapagerias*, *L. rosea* and *L. alba*. The finest plants of both kinds I have ever seen were planted out in rough loam, peat, and sand, with plenty of drainage, and they were perfectly saturated with water while making their young wood. The white one is rather slow at starting into growth, but when it does begin it grows as freely as the red one.

Fuchsias and climbing Roses I have long found excellent in the conservatory, and when they cannot be planted out in borders they should be grown in boxes or tubs of a good size.

*Plumbago capensis* is also useful, especially after it has become established, as then enough flowers are produced to make the plant ornamental, and plenty to cut from besides.

*Acacia Riceana*, noticed in your pages lately, is a grand climber. Large quantities of its graceful shoots can always be cut away when in flower without ever being missed.

What the *Passifloras* are in the stove *Tacsonia Van-Volxemii* is in the greenhouse—free-growing and excellent.

The old *Cobaea scandens*, which is a favourite in some greenhouses, often grows too rampant, and it supplies nothing for the flower vases. Its variegated form, however, is attractive from its pendant sprays of lively foliage, and is suitable for drooping from the roof of a lofty conservatory.—PRACTITIONER.

### PRUNING SHRUBS IN WINTER.

SUMMER is generally admitted to be the best season of the year for pruning shrubs, yet much experience has shown me that most Conifers and evergreens may be cut without injury during the winter months. At whatever period the pruning of ornamental trees and shrubs is done it must be done tastefully and carefully—as carefully, in fact, as is the pruning of well-trained fruit trees.

Some there are who have such strong objections to the pruning of shrubs in winter that they will not allow a few sprays to be cut for the decoration of churches and rooms at Christmas. At this period of the year there is much "hacking and slashing" of evergreens, which is most objectionable, but because work is occasionally done in a bungling manner is no reason why it should not be done at all. As a rule the pruning of shrubs is either not done at all, or it is carried to an extreme. We either find one shrub spoiling its neighbour for the want of pruning or thinning, and the beauty of both restricted; or we find pruning carried almost to the point of shaving, resulting in a chilling display of stiff and formal "round heads." In a few—very few—gardens this mode of pruning is permissible provided it is done well: in other gardens a dense intermingling thicket of evergreens may be appropriate, and the knife may be banished altogether; but these instances again are only few. In the majority of gardens timely thinning and moderate and well-executed pruning of shrubs would add much to their beauty. Such pruning may be done now. I allude to the subject because Christmas is near, and when many, especially the young and the fair, are anticipating the pleasure of wreath and festoon-making in obedience to the old fashion of greeting and celebrating the great festival. By pruning evergreens now we not only do not injure the specimens, but improve them, and in addition we give pleasure, joyous and wholesome, to many who are waiting—almost longing—for the prunings.

For several years I was gardener to a clergyman—an excellent man, who had an excellent collection of shrubs. These shrubs he cherished, but so great was his antipathy to pruning them in winter that he would not allow them to be cut either for the Christmas decoration of his house or the church. Rather than do this he would, and did, purchase large quantities of evergreens from and for others for use during Christmas-tide. That clergyman, like most others, was honest in his convictions, which are, perhaps, too often interpreted by outsiders as being merely eccentricities. Eventually this fine

collection of shrubs became the property of another clergyman, and who also prized them highly. He was not disposed, however, to purchase evergreens for Christmas decoration when he had so many shrubs growing in his garden. The time of pruning was consequently changed. Instead of being done in summer it was done in mild weather during the autumn and winter, and the "prunings" were distributed at Christmas. The shrubs have now been thus pruned for ten years, and not one of them has suffered. They are as perfect and handsome as ever, and sprays from them have decorated hundreds of homes.

In pruning shrubs in winter the work must be carefully done. The cuts must be smooth and clean—no breaking over the knife—and should be made on the underneath sides of the branches as much as possible. Shrubs which are regularly and slightly pruned to keep them shapely do not require to have more than a few short sprays removed annually; and these small sprays of Holly, Box, Laurels, &c., are exactly suitable for wreathing, and are always welcomed by many who take special delight in carrying out the good old custom of evergreen-decoration at Christmas in a tasteful manner.

Venerable customs have deep root in the national mind; they are appropriate to an old country like our own, and certainly this one—evergreen decoration—is not likely to decay, for it is in the keeping of the youth—sturdy and gentle—of each succeeding generation. The joyousness of youth is healthy—healthy to all. A source of pleasure so pure, and even artistic as "Christmas decorations," is commendable. Let us foster it so far as we can, and not restrict it by the fear of any fancied injury resulting to the shrubs. Careful reasonable pruning of shrubs in winter does not and cannot harm them, while the prunings are "Christmas gifts" costless almost to the giver, yet highly prized by the eager recipients who bear them away in triumph, for they are to them (the young) the first evidence that Christmas has really come—the first expression of "good will," which for eighteen hundred years and more has been particularly identified with the festive season. I would not have the shrubs injured, but improved; and when we can improve the garden and beautify the "church and home"—I like that alliance—I cannot help thinking that it is worth while our doing so. The pleasures of the garden are then taken into the dwelling, the garden becomes a reality and is cherished, selfishness is forgotten, unity reigns, and the result is to all who can enjoy it—a "merry Christmas." Now, as my last words, I say Prune judiciously; decorate tastefully.—A RETIRED GARDENER.

### PLUMBAGO ROSEA.

Among the many plants adapted for the adornment of our stoves and intermediate houses at this dull season of the year, none is more worthy of cultivation than the *Plumbago rosea*, and I think I may say none is more neglected. If we find it in a collection of plants at all it is in a straggling condition, placed in a corner out of the way, and grown in a pot containing soil only sufficient for the plant to eke out a miserable existence, or it is dropped in amongst other plants and allowed to push up its racemes of glorious flowers to view as best it can. And why is it? Is it because the plant is not a novelty? Is it because it is not adapted for cutting purposes? Is it because it is difficult to grow? Is it because the plant is not capable of producing a good display of flowers? Has it not a pleasing colour? Is its season of flowering of short duration? Is it not sufficiently known, or why is it? For my own part I am at a loss to know the cause of its neglect.

The plant is certainly not a novelty, as it was introduced in 1777. For cutting purposes it certainly is not well adapted, except in cases where flowers are merely required for an hour or two, when it may be advantageously used; but on the other hand, where flowers are expected to last for two or three days in a presentable condition, it would be folly to expect the *Plumbago rosea* to endure for such a time, as the flimsy flowers soon succumb after being severed from the plant. It is true all the flowers of a raceme do not wither and fade at once, but those left are not sufficient to recommend it for general cutting purposes.

In point of culture it is one of the easiest to grow of all stove plants, and only requires to be grown in quantity to produce a charming effect. Its colour is of the most pleasing hue, and its season of flowering extends over four months, but although the plant has already been in cultivation one hundred

years, I question very much if it has been grown in sufficient quantities to recommend it for general cultivation, otherwise we should meet with it more frequently and in larger quantities, as it is only by growing it in quantities that its full beauty is realised.

After I undertook my present duties in January of last year, I busied myself about the furnishing of all the walls with plants of climbing habit. The walls which puzzled me most were the walls of the Melon houses, there being no accommodation for planting anything out, and the narrow stage over the return pipes against the wall being merely wide enough for 8-inch pots. It occurred to me to cover these walls with *Ficus repens*. This would have succeeded well undoubtedly, but my ambition was to cover the walls with flowering plants, and I thought that *Plumbago rosea* might possibly be suitable. It was a happy thought, and some old plants being at command these were cared for, and cuttings were procured and propagated. As soon as rooted they received liberal attention by way of potting, light, heat, moisture, and weak applications of liquid manure. The plants were never allowed a check, but were hurried on into the 8-inch pots as soon as ready, the shoots being occasionally pinched as required to induce side shoots, which were freely produced, and by the middle of November the plants were from 6 to 7 feet high, and covered with their charming flowers. Although I had grown the plant more or less for years, still I really did not anticipate such a glorious reward for the little trouble bestowed on these plants, for they continued flowering most freely until the month of March. During the time they were in flower numerous gardeners called here to see the gardens, and I could not avoid noticing the astonishment of one and all on seeing such a charming display of the old *Plumbago rosea*. The plants were not tied in closely to the walls, but were allowed to hang out from 1 to 1½ foot over the passage, which considerably enhanced their appearance, their long, arching, pendulous racemes of flowers being thus shown to advantage.

The same walls, 60 feet long, are now covered with plants which have for the past month been producing thousands of flowers equally as fine as last year, and so long as I have walls to cover so long shall I find room for a few plants of my old friend *Plumbago rosea*. The plant is not at all particular as to soil; those plants now flowering are growing principally in road scrapings, and are well fed with liquid manure. *Plumbago rosea* is also a very clean plant, seldom being attacked with any insects except thrips, which should be well watched for, as they increase on it very rapidly. Scale sometimes infests it, but is easily kept down.

I have tried all sorts of experiments with the plants, by subjecting them to various temperatures before the flowers expanded in hopes of getting them to keep well after being cut, but no attempt has nearly succeeded sufficiently for me to recommend the plant for cutting purposes; but for the decoration or furnishing of stove or intermediate houses with flowers at this dull season of the year the *Plumbago rosea* stands second to none, but on the other hand, in my estimation it rivals many plants that we have long prized.—JAMES OLLERHEAD.

[The plants referred to were noticed in our columns last week. We never saw a wall more beautifully furnished.—Eds.]

### NOTES AND GLEANINGS.

We have received from Mr. J. Sinclair, gardener to Sir H. D. Ingilby, Bart., Ripley Castle, Leeds, a GARDEN DAY-BOOK, which he has found of very great use. The book consists of 365 pages, and is so arranged that the value of the vegetables, fruits, and flowers supplied each day from the garden can be expeditiously entered. Full lists of vegetables and fruit are printed on every page, and only the value of each day's supply requires to be added to the money column. There is also a space for "weather observations" and "general remarks." We agree with the compiler that such a book if neatly kept would be useful to gardeners generally, also to owners of gardens; but the difficulty, as it appears to us, would be in keeping it "neatly," for it is not everyone who can insert figures clearly in spaces only slightly exceeding a sixteenth of an inch between the lines. If a second edition is called for we advise that the pages be made larger and an additional column be added for quantities. We think also the total amounts of each section should be provided for, and so arranged that the entire amount of each day can be carried forward to the next. The book, however, as at present arranged is concise and in-

expensive, and managers and owners of gardens may well adopt it as one of their New Year requisites.

— THE best-grown PRIMULAS that we have this year seen are in the gardens of Munster House, Fulham. The plants, which are in small 48-sized pots, are from 18 inches to 2 feet in diameter, and are about 18 inches in height. We counted on one plant 150 expanded flowers of superior quality. The seed was obtained from Mr. B. S. Williams of Holloway, and the plants are alike creditable to the seedsman and to the cultivator, Mr. J. Pithers.

— We have received from Mr. Wipf, gardener to R. Clayton, Esq., Lincoln, a very fine head of *POINSETTIA PULCHERRIMA*. When placed on a sheet of paper and a circle was drawn touching the points of half a dozen of the principal bracts the diameter of that circle was  $17\frac{1}{2}$  inches. Forty-one bracts surrounded the central corymb of forty-one flowers, the principal bracts being  $2\frac{1}{2}$  inches in diameter. The foliage sent was of the deepest green, one leaf measuring  $9\frac{1}{2}$  inches in length and  $6\frac{1}{2}$  in breadth. The petioles of the leaves and bracts were of a deep red colour, indicative of superior cultivation. Mr. Wipf also sent prunings of Lady Downe's and Muscat of Alexandria Vines. The young wood is not so remarkable for its size as its density and its small speck of pith. The wood (which is as hard as Oak) is three-quarters of an inch, the pith being only one-twentieth of an inch in diameter. We shall expect to hear of such excellent wood producing superior Grapes.

— AN useful hint may occasionally be derived from humble sources, and we lately noticed a plan in a cottager's dwelling of KEEPING CAULIFLOWERS which is not known or practised by every gardener in the three kingdoms. The owner of the cottage was desirous of having Cauliflowers for Christmas, and five weeks ago cut some close heads, and which are now as fresh and firm as ever. These Cauliflowers are suspended in a cool pantry with their stalks or cut parts upwards. The stalks are hollowed out by scooping away the pith, and the cavity in each is filled with water. As this is absorbed or evaporated it is replenished, and the result is that the heads remain as fresh and firm as when cut from the garden. The owner says he has thus preserved Cauliflowers for more than two months.

— PERHAPS the value of small CONIFERS IN POTS is not quite so fully appreciated for indoor decoration as is desirable. For halls, corridors, vestibules, staircases, and similar places few plants are more suitable and effective than these. Even in conservatories the choicest of them are admissible, such as the most elegant of the *Retinosporas*, Junipers, Thujsopes, and *Cryptomerias*. Of these there are variegated forms, which are particularly attractive and are worthy of a place amongst ornamental groups of plants of a more tender nature. The common kinds of Conifers, also Hollies, &c., are also highly worthy of notice for rendering cheerful places which are too dry or draughty for stove or greenhouse plants. At this period of the year when rooms large and small, public and private, are sought to be made specially cheerful, small, trim, and elegant examples of the shrubs referred to are eminently worthy of notice as the most hardy and ornamental "Christmas trees."

— FOR the erection of a MONUMENT TO LINNÆUS 36,000 crowns have been subscribed. The monument will be erected in Stockholm, and will be unveiled on January 10th, 1878, the hundredth anniversary of the death of the great naturalist.

— AT the meeting of the members of the Paris Academy of Sciences held early in the present month the report on the experiments made by the Paris-Lyons Mediterranean Company for COMBATING THE PHYLLOXERA was read. They commend sulphide of carbon and sulpho-carbonates, which should be applied when the products of the winter eggs have descended to the roots—i.e., about July. The old Phylloxera of the roots is thus treated as well.

— We noticed last week a remarkable display of *Plumbago rosea* at Wimbledon House, equally noteworthy is the HEDGE of *EUPHORBIA JACQUINLEFLORA* (PULCHRA) now flowering in the Pine stove in the same garden. This hedge is 60 feet in length and forms a background to the Pines, the *Euphorbia* having been planted close to the back wall of the Pine pit, from whence a portion of the tan was removed and replaced with soil. The roots of the plants have, however, evidently penetrated into the tan, for on no other assumption can the wonderful growth of the plants be attributed. It is safe to

say that thousands of the shoots exceed 6 feet in length, and many we noticed could not be less than 8 feet, with foliage of the deepest green and flowers of unusual size. This "hedge" neither interferes with the Pines nor anything else in the house, and yields armfuls of brilliant sprays. In such profusion are they that a cartload could be cut if required. Mr. Ollerhead has in another column detailed his mode of growing the wall of *Plumbago rosea*; the history of this remarkable "hedge of *Euphorbias*" would be no less welcomed by many readers.

— IN addition to the donations already announced, amounting to £105, which have been offered to the NATIONAL ROSE SOCIETY, Edward Mawley, Esq., of Lucknow House, Croydon, offers 5 guineas for twelve Tea Roses, and J. F. Curtis, Esq., of Chatteris, £1 1s. towards a special prize for the best twelve Roses.

— FROM the recently published report of the Metropolitan Board of Works we find that the PARKS, GARDENS, HEATHS, and COMMONS under their control comprise an area of 1,094 acres, for which the Board had paid £313,859, and repaid £66,538. The interest upon the balance unpaid and the cost of maintenance of all these parks and open spaces amount to a charge upon the ratepayers of only one farthing in the pound.

— A NOVEL and interesting EXHIBITION OF ARTIFICIAL FLOWERS AND FRUIT is proposed to be held in March next at the Crystal Palace, when valuable prizes will be awarded to the most beautiful and natural specimens of imitative floral art. The classes will comprise flowers (wild and cultivated), Ferns, and fruit, and will be so arranged as to provide for competition amongst amateurs as well as amongst manufacturers. Another new Show will be one of Auriculas, which will be held in the early spring.

— MR. GEORGE HOLLIDAY, the gardener at Castle Hill, Bletchingley, informs us he has some very fine *POINSETTIA PULCHERRIMA*s in bloom, measuring some 15, 16, and  $17\frac{1}{2}$  inches across them. The bracts are some 2 and  $2\frac{1}{2}$  inches wide. They are grown in 6-inch pots. Such specimens are very noteworthy.

— THE fourth annual festival of the GARDENERS' INSTITUTE was held in the Central Hall, Darlington, on the 11th inst., when about four hundred persons sat down. After the tables had been removed, the Mayor (Mr. T. R. M. Plews) took the chair, and stated that the festival originated with the young men connected with the Gardeners' Institute generously founded some years ago by Mr. Edward Pease. The festival had prospered so much that this year it had been found necessary to engage the Central Hall in place of the Mechanics', previously used. He hoped that it would be maintained annually, and that as large a company might be present as were there that evening. Whatever funds accrued were used for the benefit of the Institute. A great part of the credit of the success was due to Messrs. Ford and Taylor, the honorary Secretaries, and to Mr. W. Hodgson, their Master of Ceremonies.

— THE ARBORICULTURAL SOCIETY OF BELGIUM will have its yearly meeting at Ghent on January 21st next. Besides the formal proceedings there will be two discussions—1, On the merits of the varieties of Pears; 2, On the disuse of pruning fruit trees.

— A CORRESPONDENT writing from the neighbourhood of Gosport, states that ROSES ARE BLOOMING VERY LATE. He gathered from his garden during the present month many blooms of Gloire de Dijon, also Devoniansis, Duke of Edinburgh, John Hopper, Turenne, President Willermoz, Perle de Lyon, and Céline Forestier.

— MR. R. W. FOSTER writes to us as follows relative to DESTROYING WEEDS ON GRAVEL WALKS:—"I use a solution of Calvert's No. 5 carbolic acid, 1 part acid to 100 parts of water, applying it with a watering-can. As the solution removes the paint from the outside of the can if spilt on it, I use a plain unpainted can." We have other testimony that carbolic acid is an effective weed-destroyer.

— A GREAT increase in the importation of POTATOES has occurred this year. The value is £1,631,808, and last year in the eleven months £941,480.

#### CAUTION.

NURSEYMEN are most liberal and honest men, but the commodities sent out are not always true to name. My two favourite hobbies are Roses, of which I have over 2500, and Peach

and Nectarine trees 183 in number. It is of no use sending me one thing for another. I am sure to find it out. I have had Old Roman Nectarines sent for Royal George, and Princess Clementine (summer Rose, white; very beautiful) sent for La Tour d'Auvergne, a red summer Rose. Now I am sure that the nurserymen who sent the above were not aware of the mistake. I can only account for these mistakes by the carelessness of the propagator, or by the "larking" habits of improvers, who are permitted to propagate, but who "lark" during propagation.

N.B.—Do not turn off your propagator till the season is over, and have a book to depend on instead of moveable tallies.  
—W. F. RADCLIFFE.

### APPLE ELECTION.

Now that the election of Apples is mooted, what have the readers of our Journal to say about the project being carried into effect? As with Roses so with Apples. That there will be an amount of labour and anxiety about an election there can be no doubt, and who will lead the van and be the returning officer? Mr. Robson has well ventilated the question, but my own opinion is that three classes will answer the purpose required—namely, earliest, midseason, and latest kinds. Apples vary, some doing well in one place, some in another. Locality, circumstances, climate, and situation have much to do with their well-doing. I have known in some seasons Apples which have kept well, and in others the same sort have not kept well at all. I have known when Striped Beefing and other useful keeping Apples, after being carefully stored, have gone off with a disease like dry rot; other seasons they have not been affected at all. Early Apples in some seasons have kept for months, at other times they have speedily decayed; so that under some circumstances it becomes a difficult matter to say when they are in and out of season. Then, again, we northmen are sometimes inclined to envy our more favoured southern brethren, yet they say we need not do so. No doubt they have their difficulties as well as we have, yet we have an idea that the climate of the south on the whole is more favourable than that of the north; nevertheless, by all and every means let us have the election.—PYRUS MALUS.

### EUCALYPTUS GLOBULUS.

THE information supplied from Ireland to the hardiness of this beautiful evergreen has in the majority of instances been favourable. However, in my case I regret to record a total failure. Three plants 5 feet high I planted out in warm situations sheltered from the north-east winds on the east coast of County Down. In two years those plants attained the height of 20 feet. In February of the third year, during a long period of snow and frost, the splendid foliage gave way and the trees became leafless, with the extreme ends of the branches blackened and dead. They never recovered. A similar fate was the lot of many more, and deeply did the owner regret the loss.—JOHN BOYD, *Co. Dublin*.

### RENEWING OLD VINES.

WITH the exception of a few late sorts all Vines will now be at rest, and those which have not done well throughout the season should now be under consideration as to what is best to do with them. If they are very old Vines, and seem quite exhausted, many would recommend that such be rooted out altogether and be replaced with young canes. Under certain circumstances perhaps this would be the best thing to do; but I am inclined to think that rooting-out and planting afresh is not always the most profitable way of disposing of old Vines.

Several cases have come under my notice lately where the old Vines had annually been decreasing in strength and fruitfulness until the young shoots were no thicker than straws and the bunches little larger than Black Currants, and these same Vines are now producing wood and fruit equal to the best five or six-year-old young Vines; and with this advantage—that they bear as much fruit the second or third year after being renewed as a young Vine would be capable of doing the fifth or sixth year. Young Vines are generally planted two years before they bear fruit, and, as a rule, they only bear a bunch or two the third year, while it takes them another year or two to be in bearing condition the full length of the rod or rafter. Old Vines have no leading cane or spurs

to make, as they are always the full length of the rafter, and all they require is something to put fresh vigour into the old wood, and this may be accomplished in the following manner:—

When the Vines are quite dormant, if the roots are outside, begin by digging a trench along the border 4 feet deep and 8 feet from the front of the vinery. When this has been taken out 3 feet wide take another trench out in the same manner, and in doing so be very careful to preserve the roots as entire as possible, and place them as they are laid bare up towards the stem. The soil must all be taken out to the depth of 4 feet until the whole Vine can be lifted away. The bottom of the border will then be clear, and if the drainage is not naturally good place a layer of rough broken stones or bricks to the depth of 6 inches all over the bottom. Where the roots are inside the house serve that in the same way, and then fill up to within 18 inches of the surface with a mixture of good loam and ground bones. During these operations the roots should be tied-up in a damp mat, and as soon as the border has been filled up to the extent stated, take the Vine and place it where it has to grow, then spread the roots all over the surface of the new soil, and cover them carefully up to the original level of the border with the best of the soil. Place about 2 feet of long dung and fresh leaves over the newly-made border, and for the first year do not push the Vines into growth with much fire heat, and when they do make shoots let them grow from 2 to 3 feet long before stopping them; and if all the bunches are cut off as they appear the first year, the second year's crop will be all the better for it. After the wood has been well ripened the Vines may be rested as in former years, and the crop the following season will be little, if anything, inferior to the best they ever produced, and they will continue on for years to bear like young Vines.

I have seen old exhausted Vines treated at the roots as above described, and the rods cut off at the lowermost spur, send fine strong canes up to the top of the rafter the first season.—VITIS.

[So have we.—EDS.]

### THE GARDENS AT BUCKINGHAM PALACE.

JOHN SHEFFIELD, Duke of Buckingham, built a house in 1703 on the site where the Palace now stands which bears his name. This Palace was commenced building in 1825 from designs furnished by Mr. Nash, and many years passed before it was completed. The area of the gardens is about fifty acres, of which there are about twenty-five acres grass. There is a considerable breadth of ornamental waters, islands, rustic bridges, magnificent trees and shrubs, that one might believe one's self to be a hundred miles in the country among the most beautiful natural scenery were it not for the distant and rather faint rumbling of the traffic in the adjoining streets.

The gardens lie to the west of the Palace, and in the Georges' time the site which they occupy was devoted to dairy purposes, but the late Prince Consort had the ground laid out in the English style, and always had the gardens kept in a fit condition for the reception of royalty.

That part of the lawn which adjoins the Palace is kept quite open, not a tree nor bush interrupting its level expanse of turf. On this grassy carpet cricket, football, and other games have been played during years past, and the Royal Family can call to mind many happy scenes of their youth. Where the lawn becomes first broken in its continuity there is some breadth of ornamental water well stocked with waterfowl, amongst which are many rare exotic species. The waters are varied with islands and plantations, which are connected together by rustic bridges; and on the shore most remote from the Palace are some grand forest trees, Oaks, Elms, Planes, Beeches, Poplars, Limes, and other trees of stately growth, some of which sweep their lower branches grandly over the glittering surface of the waters, others towering upwards, and their tops are reflected in the clear surface of the lake. The Queen, when the weather was fine, used to breakfast in the open air under the shade of the trees that fringe the ornamental waters. Beyond the water there are thickets of choice shrubs, deciduous trees, clumps of Rhododendrons, and other evergreens. The richness of the miscellaneous gathering is peculiar to the spot.

We next come upon wilder scenes. Sometimes we are hemmed-in between thickets, and anon are enjoying a charming view from the crown of a hill, and again find ourselves in a deep hollow among Ferns and grasses or a tangle of flowering

and trailing plants. On the more level part of this varied surface there are many noble specimens of trees and shrubs. The undulations terminate in one direction in a mound upwards of 100 feet high, and although artificial, it is so managed that it seems to be quite natural, and it acquires its naturalness and its beauty from the soundest rules of art in the formation and the planting.

The shady walks and cool retreats which necessarily accompany this picturesque style were a constant source of enjoyment to the late Prince Consort when staying at the Palace. Some of the walks are quite arched over with Laburnums, Honeysuckle, Guelder Roses, and scarlet-flowering Thorns, which were planted by the Prince's hand, and among and under these he would oftentimes lead his children at early dawn to hear the song of the thrush or the blackbird. The Prince was intensely fond of birds, and these gardens are numerously

peopled by the feathered songsters, for it was a place of privilege to them. Not a nest was ever knowingly disturbed, and it was the constant aim of the Royal father to teach his children to show tenderness to helpless creatures, and it has been exemplified in all the Royal Family. The children were also taught to take an interest in flowers, and had each their own little garden, which was a source of great delight to them, where they learnt the names of those flowers which were dear to them, because themselves had planted, watered, and watched them. Healthy exercise in gardening is indeed recreation, natural, simple, and pure, which may be enjoyed in all stages of society from the prince to the peasant, bringing blessings to the palace and peace to the cottage. Gardening improves the heart as well as the taste; it refreshes the body and lightens the spirits, and the more refined the taste the more exquisite the gratification that may be enjoyed in every cherished garden.

Fig. 77.—BUCKINGHAM PALACE GARDEN.

Bedding plants are of course used in the Buckingham Palace gardens, and some of the most agreeable effects are those produced by isolated masses or small groups of detached beds, which afford scope for only a few simple colours. There is, however, a geometric garden proper, which consists of a grand circular scheme of nineteen beds which I have seen effectively arranged, planted with choice and suitable plants, and kept with scrupulous care.

The conservatory is on the north side of the Palace, and, like it, lacking elegance, and unfortunately not at all well adapted for the growing plants, and to keep it in good order the plants must be frequently changed. I have seen it look very beautiful in the autumn with Chrysanthemums of both the large varieties and Pompons, grouped with specimen shrubs and fine-foliated plants so as to form the most attractive features of a picturesque scene, in which they appear to greater advantage than when exhibited by themselves.

The Chrysanthemum is a favourite flower of all classes, and it is one of the flowers admired by our Queen; Chrysanthemums are therefore extensively grown out of doors in these gardens. They peep up amongst the shrubs, fringe the walks, cover the banks, and make the whole place gay as if wholly devoted to this autumnal flower, which it is not, for there are displays of all kinds as the seasons revolve. Let it suffice, then, that horticulture is fairly represented. Mr. Humphrey,

late gardener at White Lodge, Richmond Park, is the gardener at Buckingham Palace. He was appointed about three years ago, and succeeded the late Mr. George Wyness who died in harness, and like him is a very estimable man.—N. COLE, Kensington.

#### MUSCATS ON THE EXTENSION SYSTEM.

I HAD long ago cherished a notion that I could grow Muscat Grapes if I only had an opportunity to do it my own way, and six years ago such an opportunity presented itself with the result shown in the engraving.

The Vines were planted on the 22nd of June, 1870, and had been raised from eyes the same season. They were placed about 7 feet apart on each side of the house; they all grew well, and carried a bunch or two the year after planting. This was more to check over-luxuriance than for the sake of the fruit, as we had Vines planted temporarily along the centre of the house for supplying fruit at first. The permanent Vines, notwithstanding rather heavy cropping and root-pruning, grew very vigorously, and two years ago it was a question whether to go on mutilating them still more severely, or destroy some of them and allow those remaining to have a more natural extension. I decided on the latter method. A Vine near each of the four corners of the house was brought down to a hori-

zontal position, and shoots were trained at right angles from them in the spaces between the other Vines, and they have now so completely furnished the whole compartment that all others will be removed. It is very probable, according to present appearances, that in another year or two the number will have to be still further reduced.

The growth these four Vines have made is I think somewhat remarkable, the circumference of the largest stem being 13 ins., and that of the smallest 10½ inches, measured just above the ground; at 2 feet 6 inches from the ground the largest measures 8½ inches, and smallest 7½ inches. The size of this compartment is 80 feet by 30, and each Vine runs half the length.

Fig. 79.—MUSCATS ON THE EXTENSION SYSTEM AT LONGLEAT.

The opposite side to that shown in the engraving had the number of plants reduced to four last spring with very satisfactory results. A photograph of that side was taken, but as it was from the other end, and consequently in opposition to the sunlight, it did not come out satisfactorily.

So much for the growth of wood, now what about the fruit? Well, all the fruit is, perhaps, above the average for Muscat

Grapes, but that on the restricted rods will bear no comparison with the rest. It did not colour so early nor so well, and is inclined to shrivel in places, while that on the large or extension Vines is perfect in every respect. This is not because the large Vines are not carrying a fair crop—they ripened from fifty to fifty-three large bunches each, which average considerably over 2 lbs. a bunch; but it is, I am convinced, because they are

grown in a more natural manner, and the fruit is all produced on young wood, which always has the best perfected eyes.

I have described my treatment of Muscat Vines in previous numbers of the Journal. It differs chiefly from the general practice in having less fire heat, the temperature often being as low as 55° at all stages of growth; there is no syringing at any time, not even at starting, no artificial setting beyond a gentle tap on the trellis, abundance of water is given to the roots both in winter and summer, and the ventilation is attended to as soon as the sun touches the house. A sun temperature of 80° to 90° is always desirable, but it is essential to have the greatest part of the rise after the ventilators are open.

In conclusion, I have to say, that although I believe I am going in the right direction to grow Muscats, I consider I have as yet only half succeeded, and that nobody knows what may be done with this noble class of Grapes when we once set aside our old-fashioned notions about its being difficult to grow and requiring an extraordinary amount of fire heat. Muscats and other light-coloured Grapes require more sunlight than black Grapes require, but not more heat.

All fruits, in my opinion, are better when the plants which bear them are allowed to extend somewhat every year.—WM. TAYLOR.

## NOTES ON VILLA AND SUBURBAN GARDENING.

**CUCUMBERS.**—Those who require early Cucumbers, and have no other convenience for growing them than by dung heat, must now commence operations, as it takes a considerable time to prepare the materials. It is the best way to use a small frame for raising the plants, as less manure is then required, and less cost is incurred in keeping up the requisite heat. Again, by raising the plants and having them well advanced in a single-light frame materials for a larger frame or bed can be prepared, and the season being then a little more advanced the plants may be expected to do best in the last-made and largest bed; therefore lose no time now in preparing sufficient manure as will make a fair-sized bed. After the manure has fermented it should be repeatedly turned and well mixed in order that the rank steam may escape, and then when put up all parts of the bed will heat alike and settle down regularly. I use a third of good oak leaves with the manure; but these are not absolutely necessary, and many amateurs are not able to obtain leaves.

When the rank heat has escaped and the manure is sweetened measure the length and breadth of the frame, and set the bed out a few inches wider all round. The bed ought to be 5 feet high at the back and 4 at the front. First of all, however, a layer of faggots should be placed at the bottom to keep the manure clear from the ground, so as not to be affected by the coldness of it. In building up the bed take care to lay the manure regularly and beat it down as firmly as can be done with the back of the fork, but do not tread it down with the feet. When high enough put on the frame and also the light; this will help to draw up the heat. Let a trial stick be thrust into the centre of the bed, and watch this regularly as the heat rises, and it will be easy to tell when the soil may be put in; but take care that the bed is not so hot as to burn the soil, for if so no plants will grow in it, and it would all have to be taken out again and much time lost. Neither should the soil be spread all over the bed, but a heap should be made in the centre of it reaching near to the glass. This will not bring the heat down very much, and it will soon become warmed through. Let the mixture be two-thirds of good turfy loam and one-third of well-decayed leaf soil.

The seeds should be sown in well-drained pots or pans in the soil that is warm. The soil should be rather dry than wet, and that for the seeds be much finer than that for the after-growth of the plants. Plunge the pots in the soil and only just cover the seeds, and it is not advisable to water for two or three days, or the seeds are liable to rot. When the plants appear, and their seed leaves are fully grown, they may be potted-off one in a pot in warm soil, and this should be done without taking them out of the frame.

When the plants have made about three rough leaves they may be planted in the bed prepared for them. The temperature must not go below 65°, but 70° would be better if it can be provided. Ample covering must be placed over the glass at night; and in order to encourage the plants to grow well the glass must be kept very clean to admit as much light and sun as possible in these short days. When the heat falls below that stated above linings of heating material must be at once applied; but this need not go through the process of fermentation like the other, but great care must be taken that the rank steam does not enter the frame, and which can be excluded by stopping up the space along the bottom of the frame with the exhausted manure. Occasionally, when the lights are slightly propped up to let the inside steam out, the steam from the lining enters there, so the mats must be put on with care, so as

not to cover the lining as well as frame, or the steam is conveyed inside the frame. The manure for the linings must be well mixed, or one part will heat more than another. It is very essential to select a sheltered yet as sunny a spot as possible for the bed, and sometimes during very cold nights or windy weather it is necessary to protect the bed with straw, or, what is better, thatched hurdles. They can be easily removed when not wanted.

When the roots of the plants show through the soil a thin layer of soil should be added, previously warmed, so as not to cool the atmosphere. Also let the water be warmed before it is applied. No manure water will be needed until the plants are fruiting. The above are the principal directions for the management of a dung bed, and if carried out carefully cannot fail to prove successful.

As to sorts, many grow what they call their own sorts with local names, but a good form of Telegraph, such as Paul's or Rollisson's, Monro's Duke of Edinburgh, the old Sion House, Lord Kenyon's Favourite (a small but wonderfully prolific sort), and Master's Prolific, are all suitable for early produce.—THOMAS RECORD.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### HARDY FRUIT GARDEN.

It will be time to see that the pruning and nailing of wall trees is proceeded with as soon as possible if it is not already done. All the hardiest trees should be pruned first. Pears and Apples will take no harm, nor in ordinary seasons in the south of England, especially in dry districts, will the trees suffer; but those who have only had experience in such districts are not in a position to dictate to gardeners where the rainfall has been nearly double with a corresponding want of sunshine, which has caused the young wood to be overcharged with moisture, and consequently much less able to resist frost. Under such unfavourable circumstances much may be done by an efficient system of draining and border-making—indeed, it would be useless to try the cultivation of the finer fruits without this preparation, and all trees which are subject to gumming ought to have good well-drained borders for the roots to work into. Those who have had experience with wet low-lying districts will probably prefer to wait until all danger of severe frost is over before pruning their trees.

The training of Peach and Nectarine trees is seldom well done by amateurs. Notwithstanding all that has been said and written about different systems of management, there is no better mode of training than that which has been the custom for so many years in all well-kept gardens—namely, the fan method. The object of the cultivator is to encourage the growth of young wood disposed as regularly as possible all over the wall, and to cut out old wood where it is not required, replacing it with healthy young wood of the previous year. Should very severe frost set in after the present wet and mild autumn much damage may be done to both the old and young wood, and the work of the pruner and trainer might have to be done over again, and the trees would suffer much more severely after they had been pruned and trained than if nothing had been done to them. A little delay, therefore, in pruning these tender fruits may be advantageous.

Plum and Cherry trees suffer much from gumming in such seasons as the present, and when an apparently healthy branch is badly gummed it is better to cut it off at once at the injured part than allow it to remain to die, as it were, a lingering death by strangulation. Such branches sometimes do not show any injury now, but will do so two months hence. The same may be said of Apricots. The young wood seldom suffers, but large branches die off at any season and without apparent cause. Pruning may be done in the following order—first Apples, then in succession Pears, Cherries, Plums, Apricots, Peaches, and Nectarines. Many of the old gardeners used to unfasten their Peach and Nectarine trees from the walls at this season and secure the branches to stout poles, which had the effect of considerably retarding the blossoming period, and gave a better chance to resist early frosts. The branches should be nailed to the walls about the end of February. When it is necessary in pruning to cut-back the young wood of Peach and Nectarine trees it ought always to be cut to a triple bud, as the middle bud of the three will be a wood bud. Triple buds are not usually found on the weakest wood, but only on that which is strong or moderately so. If there are no such buds it is better not to cut-back the growth at all.

We have not done much in this department during the past week except in continuing the pruning of Gooseberry, Raspberry, and Red Currant bushes. After clearing away the prunings we are now giving a dressing of manure, and will proceed to fork it in the ground as soon as we can do so. If Strawberry beds have been neglected the weeds will have made considerable progress, and they cannot be better disposed of than by picking out the largest by hand and giving a dressing of ma-

nure between the rows, afterwards forking the manure and small weeds under ground.

#### CUCUMBER HOUSE.

So far our plants have done well, and they will continue bearing as much as we require through the winter months, but the strain upon plants which have been in bearing for the last two months is trying to their constitutions. We shall sow more seeds or strike cuttings about the first week in the new year; and when the plants are strong enough to plant out, those that are worn out by winter bearing will be removed to give places for young plants. Our houses are well heated, and it is not difficult to keep up the temperature to 65° or 70°. In circumstances not so favourable, and where it would be necessary to overheat the pipes to maintain this temperature, it is much better to have some covering for the glass. An ordinary canvas screen thrown over it will make a difference of at least 5° in the night temperature. This will not only be a saving in fuel, but give also a more congenial temperature to the plants. About the shortest day in the year is the time that the plants require the greatest amount of attention. They must not suffer for want of water, nor must too much of it be applied to the roots. At a time when the sun scarcely shines at all, or if it does it is only "to blink a wee and sink again," its influence is scarcely felt on the temperature of the house. Still, unless there is a cutting frost wind we always manage to open the ventilators just a little at the highest part of the house for a few hours at mid-day. This daily change of air is very beneficial to the plants, and with care it can generally be managed without making any appreciable change in the temperature. We keep up a bottom heat of 85° by two rows of 3-inch pipes placed about 2 feet below the surface of the bed. We have found that by using all the evaporating troughs the atmosphere became too moist and caused a weak watery growth, but by using only one trough a more healthy growth was apparent. Should any thrips appear have the house smoked at once with tobacco. The leaves will not endure too much of it, and it is best to fumigate moderately three times at intervals of three days than to run the risk of injuring the plants by one very strong application of smoke.

#### GREENHOUSE AND CONSERVATORY.

When the *Chrysanthemums* go out of bloom there is considerable difficulty to supply their place, but gardeners with limited room will be glad to remove them, as they take up much space and do some damage to hardwooded plants. *Cyclamen persicum* is a useful and well-appreciated plant for producing flowers from now until the end of March, and by that time spring flowers, consisting of Dutch bulbs, will also be over, to be succeeded by different sorts of forced shrubs, *Roses*, &c. Hardwooded plants of different species require attention now, and time can be better spared for tying and training the plants at this season than at any other. Plants of *Azalea indica* are now shedding their leaves, and require to be gently shaken occasionally to free the plants from those ready to drop off. Thrips are very destructive to the *Azalea*. Persistent fumigation will destroy those insects, but in some cases it is not convenient to fumigate; then they may be destroyed by dipping the plants in a mixture which will also free them from any trace of red spider, which no amount of fumigation will destroy. Many of the mixtures advertised in this Journal will destroy thrips if applied according to the instructions which are given; but those who do not find it convenient to obtain such will find a certain remedy in the following:—To one gallon of rain water add 6 ozs. of soft soap and half a pint of tobacco liquor; put it in a pot and place over the fire until the water boils, let it simmer for ten minutes, and when cool the mixture is ready for use. With this syringe the plants after they have been laid on their sides, as the water running into the pots, if the plants were in an upright position, would injure the roots.

The damp weather has been injurious to some plants, causing mildew and mould. Sulphur, applied as directed in previous numbers, quickly checks the spread of mildew, and destroys it. The fires may be lighted by day, especially after watering. At such a time the ventilators must be open to allow moisture to escape. During the prevalence of dense fogs, so common at this season about London, it is better not to open the ventilators at all, and the application of artificial heat at such a time would be injurious rather than otherwise. All softwooded plants require to be regularly looked over, picking off any decaying leaves, and in the case of plants intended for large specimens tying out the growths. See that no insect pests form a lodgment on stage or fancy *Pelargoniums*, *Cinerarias*, or herbaceous *Calceolarias*. If these are thoroughly cleaned now, and kept clean during the winter, the plants will be healthy and give little trouble during the busy period of the year, when such work is apt to be neglected.

#### FLOWER GARDEN.

In calm weather the lawn should be thoroughly cleaned by raking and sweeping the leaves up from every part of it. Those that have found a lodgment in the shrubby borders must also be thoroughly cleared out of the most difficult places, else gusts of wind will on another occasion sweep them out on the lawn

to cause extra sweeping, which would otherwise not be required. In large places this gathering-up of leaves takes up much of the gardener's time at this season, and the leaves collected are not of much value, as they are frequently full of decaying wood, which produces fungus. Only leaves that have been collected from the open meadow or lawn should be used for leaf soil. It is better to have a fire, and burn the rakings of the borders as they are gathered; the ashes can always be used.

A coating of manure ought to be placed over the roots of *Roses*, to be forked-in after the bushes are pruned. A constant watch must be kept over hardy herbaceous plants. The more delicate species suffer from wet as much as from frost. We are confident that the shallow bottomless pans made of the same material as common garden pots would answer well to protect the tender sorts, a square of glass being placed over the pan to throw off the water, and this being tilted at one side to admit air.

Florist flowers, although they do not require much attention, cannot be neglected. The leather-coated grub has attacked the *Pink* in a persistent manner, and we have only saved the plants from its attacks by catching them feeding after dark at night. Large earth worms also get hold of the tips of the leaves, and they are strong enough to bend weak plants down and break them. It was necessary to strew the surface of the beds over with quicklime to stop their "little game." A steady frost would be much better for all florist flowers than so much wet. Tulips planted out early in November are now appearing above ground. Should very severe frost set in we shall cover them over with dry loam. Those planted later are more likely to do better in the spring. Auriculas are passing through a trying period. Every decayed leaf and trace of mould is removed as soon as it is observed. Should decay fasten on the centre of the plant its loss is almost assured. Carnations and Picotees have likewise certain severe trials to endure, even if the frames are watertight, which is not always the case. Many varieties are so subject to spot on the leaves that the utmost care cannot bring them through the winter free from this insidious disease, and it is much aggravated by the smoke and damp of London. We have this week gone carefully over the plants and removed all affected, stirring the surface of the pots at the same time with a pointed stick. Air is admitted freely on all favourable occasions to the frames of both Auriculas and Carnations.—J. DOUGLAS.

#### TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Amateur's Guide*, highly illustrated: also *Price Current of Garden Seeds, Potatoes, Bulbs*, &c.

James Carter & Co., 237 and 238, High Holborn, London.—*Vade Mecum and Seed Catalogue*, highly illustrated.

Ernest Benary, Erfurt, Germany.—*General Catalogue of Vegetable, Agricultural, Flower, and Tree Seeds*.

Joseph Schwartz, 43, Rue de Repos, Lyons, France.—*List of New Roses*.

Eug. Verdier Fils Ainé, 37, Rue Clisson, Gaze d'Ivry, Paris.—*List of New Roses*.

Louis Van Houtte, Royal Nursery, Ghent, Belgium.—*Catalogue of Gesneraceous Plants, Caladiums*, &c.

#### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

CRYSTAL PALACE (Artificial Flowers and Fruit). March 17th.

NEWCASTLE-UPON-TYNE. March 21st and 22nd. Messrs. J. H. French, Benwell House, and J. Taylor, Rye Hill, Hon. Secs.

GLASGOW. March 28th and May 28rd. Mr. F. G. Dougal, Sec.

LEEDS (Spring Show). April 2nd and 3rd. Mr. A. Walker, Neville St., School Close, Leeds, Hon. Sec.

WISBECH. June 23th. Mr. Charles Parker, Hon. Sec.

TONBRIDGE. July 18th. Mr. W. Blair, Sec.

ISLE OF THANET. August 30th. Mr. C. D. Smith, Hon. Sec.

#### TO CORRESPONDENTS.

WELLINGTONIA GIGANTEA.—"X." asks—"What is the height and circumference of the outside branches of the largest Wellingtonia in England?"

PRUNING PEAR TREES (*Somerset*).—We cannot give directions. Much depends upon the state of the trees, which have been greatly neglected.

BOILER (A. M.).—We cannot recommend one. Consult our advertisement columns and select the boiler that best suits your building, &c.

PEAR TREES DISEASED (A. A.).—They are attacked by canker, induced probably by the roots having descended into an ungenial soil.

BEST CLEMATISSES (*H. Taylor*).—Jackmanii, Gem, Alexandra, Miss Bateman, Lady Bovill, Lady Lonsborough, Star of India, and Mrs. James Bateman. You ought not to cut them down after flowering.

CAMELLIA FORCING (*Felix*).—We think you may move the plants from the greenhouse to the stove, placing them in the cooler end of the latter, where the temperature does not exceed 55°, and using a little weak manure water.

SUPPORTS FOR PEAS (*Mackenzie*).—Galvanised iron rods placed 6 feet apart, and net of the same material with very wide meshes, answer well.

EXCLUDING RABBITS (*N. J. M.*).—We have excluded them by placing near

the hedge galvanised iron netting 2 feet high above the surface, and 6 inches below it. They never burrowed under that.

**GESNERA EXONIENSIS NOT FLOWERING (E. L. W.).**—We think the cause of the plants not flowering is due to their not having a sufficiently high temperature, or it may arise from their having been started late. To do well they, after September, require a light and moderately airy situation in a stove, and to be daily supplied with water. We afford ours a temperature of 60° at night, and 65° to 70° by day, and they flower very freely. *Encyclanthes* flower less freely generally than *Gesnera exoniensis*, and we think both are grown in too low a temperature, and have not sufficient light, and are probably too dry at the roots.

**PRUNING CLEMATIS (E. W.).**—Pruning is best done in February, or so soon after as mild weather permits. In pruning, all the old wood should be thinned out, especially leaving the young shoots of last year at such distances as to cover the bed, shortening these shoots to firm ripe wood. The early-summer and late kinds require the same treatment. The best time to insert cuttings is in spring when the shoots are 2 or 3 inches long, taking them off with a heel of the old wood attached and placing in sand in gentle heat, keeping them rather close, moist, and shaded.

**LILIUM IN BEDS (Idem).**—Do not take up and replant, but top-dress with sweetened rich compost 2 or 3 inches thick. Turfy loam and vegetable refuse in about equal parts is a capital application.

**HEATING APPARATUS DEFECTIVE (R. F. B.).**—From the water being heated in the supply cistern which communicates with the lower or return 4-inch pipe shows that the water as heated by the boiler flows equally by the return and flow pipes, there being, in fact, no circulation. Are you quite sure that the flow pipe in the greenhouse is above the coil pipe of the boiler? The flow gradually rising from the boiler to the air pipe, the bend you allude to in the return pipe ought not to interfere with the circulation unless air lodges at the elbow, which we do not see can take place. It would have been better without the elbow. Satisfy yourself first that the flow pipe from the boiler has a gradual rise from it to the air pipe, and that the return pipe from the air pipe falls gradually to the return of the boiler. There can be no air in the pipe in that case, as it will rise to the highest point—the air pipe, and escape. We apprehend your pipes are on the level alongside each other, and there is no circulation because the heated water rises both by the flow and return pipes—boils in the boiler and pipes adjacent. It may be only a case of overheating, for we see nothing in the bend of the return pipe falling from the air pipe to the bend to impede the circulation. The removal of the bend and lowering of the return to meet that of the boiler is proper, but if the flow rise to and the return pipe fall from the air pipe the elbow may remain. The fault is not in it. You will easily know whether it be a case of overheating by feeling the pipes. If not, the water being driven out at the pipe is a consequence of the water in the apparatus being heated to an uniform temperature, boiling and blown off because a vacuum is caused by the generation of steam.

**STARTING PINES (W. W.).**—The large "lanky" plants are less likely to throw up fruit than the stiff strong plants, but we should nevertheless give them a trial; and, if they do not start with the others, continuing in the higher temperature, and they will probably be little later, if any, than the others.

**ANEMONE FULGENS.**—"G. S." says—"The glowing descriptions given of this plant have induced me several times to purchase tubers. Plants I have, but flowers none. Will any successful grower tell me—1st, Is it better to leave the tubers all the year in the ground, or to dry and replant them, and when? 2ndly, Is stiff or light soil the better? 3rdly, Sun or shade?" Any of our readers who have cultivated this flower successfully will oblige by sending the information asked for.

**CLIMBING PLANTS FOR WALL (J. P.).**—*Passiflora cernua* is very pretty and quite hardy except in very severe winters. *Wistaria sinensis* would be quite hardy, and would be a noble object on a 16-foot wall. You probably allude to *Clematis Jackmani*; the flowers are violet purple, large and fine. Roses will not succeed in London.

**SHRUBS FOR SMOKY DISTRICTS (Idem).**—*Aucuba japonica*, in variety; *Arbutus*, in variety; *Phillyrea media*; *Holly*, in variety; *Berberis Darwinii*, *Japan Privet*, tall-growing *Box*, *Laurus nobilis*, *Cerasus laurocerasus* (common Laurel), *Mahonia*, in variety. All the above are evergreen. The following deciduous species will be suitable—*Amygdalus communis* (the Almond), *Crataegus*, in variety; the *Flowering Currant*, in variety; *Spiraea*, in variety; *Syringa*, in different species and varieties, including the *lilac*; *Weigela rosea*. It will improve stiff clay to mix sand with it.

**ARRANGEMENTS FOR A HEATING APPARATUS (H. T. Frampton).**—Cut the existing supply pipe between the boiler and greenhouse for a junction with two valves—one to control the greenhouse pipes, and the other those in the new houses. From this junction carry a flow-pipe straight to the nearest point of the new houses, continuing it along outside so far as the partition, branching off into both houses at any convenient point, and having valves fixed in both these branches so as to enable you to shut off the heat from either compartment at will. The return-pipe could, of course, be connected with that of the greenhouse. For such small houses an extra amount of piping is advisable. A single 4-inch pipe will, however, be quite sufficient for the cool house if it is carried all round it, and a couple of the same-sized pipes running all round the hothouse will render forcing an easy matter, even in the coldest weather. Rings of vulcanised indiarubber are preferable to cement, as from their plant nature they yield to the expansion and contraction of the pipes; only make sure that your joints are rendered quite watertight in the first instance, and you need fear no subsequent failure. The elevated position of the new range points to a little future trouble in regulating the valves, it being quite clear that checking the flow to the higher level sufficient heat could always be thrown into the greenhouse. The connections between the old and new piping may be of 2-inch pipes.

**PROPAGATING CHRYSANTHEMUMS (W. P.).**—Select the stout, short-jointed, young shoots and treat them as detailed in our pages by Mr. Hall, Mr. Harding, and others. The name of the shrub is *Cotoneaster microphylla*.

**FORCING LILY OF THE VALLEY (Old Subscriber).**—We can only advise you to plunge the pots in leaves or cocoa-nut fibre refuse, covering the crowns 3 or 4 inches, and keeping in the temperature you name, or slightly increasing it, and if growth is not perceived in three weeks you may conclude that the crowns are dead in consequence of their long detention at Rotterdam.

**STOCK FOR PEACH TREES (M. C.).**—For open-air culture, or for under glass, the *Muscule Plum*. They are never budded or grafted on the Quince. You do not seem to be aware that a bud or graft will not unite to a stock not in some degree related to it.

**SUTTON'S MAGNUM BONUM POTATO (D. D. W.).**—The greatest weight of this variety from 1 lb. of seed which we remember to have noticed was 267 lbs., exhibited at Reading by Major Thoyte.

**SMALL-LEAVED IVIES (N. C.).**—The following have variegated leaves:—*Hedera marginata grandis*, *H. marginata rubra*, *H. marginata major*, *H. minor maculata*, *H. chrysophylla*, *H. argentea*, *H. aurea*, and *H. elegantissima*. Cultural remarks may be found in another column.

**DESTROYING WEEDS ON WALKS (G. F.).**—Mr. W. Sowerby of the Royal Botanic Gardens, Regent's Park, reports that for killing vegetation, and preventing its growth on gravel walks, he found that carbolic acid in very dilute solutions (No. 5 quality in one hundred parts water), was the best, retaining its effect longer than any other.

**NAMES OF FRUIT (E. M. Stone).**—217, Josephine de Malines; 163, Nouveau Poiteau; 203 and 108, Vicar of Winkfield; 95, Josephine de Malines; 54 and 55, Susette de Bavy.

**NAMES OF PLANTS (A. Boyle).**—It is a *Begonia*, and we think it is *B. coccinea*, but the flowers were smashed. (W. W.).—*Escallonia rubra*.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### BIRMINGHAM POULTRY SHOW.

It is the twenty-eighth Birmingham Show, so the catalogue announces. The schedule has been much altered and modernised, not entirely for the better. The general arrangement, we regret to say, has not been altered. The old pens are becoming so dilapidated that several serious accidents have occurred from birds breaking and fighting through their patched sides. A large number of birds including French and Hamburgs are shown in zinc pens suitable for Bantams, but so small that their inmates cannot possibly show their size or carriage. The temperature in the Pigeon gallery is towards evening unsupportable from the heat from the gas, and the whole poultry annex unpleasant from its constant escape. From the single-bird system having been adopted there is this year an increase in the entries, though a considerable decrease in the aggregate number of birds shown, as well as a decline in their quality. The changes for the better, which we are pleased to recognise, are the divisions of the adult and young birds in the Polish and Hamburgs. In the case of Polish, in which full development of the prime feature—viz., crest, is impossible in the first year, this classification is a great boon. In the case of Hamburgs we can see no use in it; they do not improve by age, neither is size a desideratum in them, consequently young and old birds can at this time of year compete on perfect equality. There are some excellent classes in the Show, notably so the *Cochins*. Probably this is from the endurance of the breed under painful circumstances, but taken all round the Show is a very moderate one, not to be compared with the Crystal Palace generally, or with Oxford in the display of Pigeons and chickens of the year. It is a pity that with all its prestige Birmingham should have descended into the rank of second-rate shows. We have before now written in its favour, but to do so further while it remains as it is would be to desert the cause of humanity towards birds.

**BRAHMAS.**—The first class were adult Dark Brahma cocks (twenty-nine entries). This was a very good class. The first was a large grand-shaped bird, with good legs and feet, well feathered and beautiful in colour. The silver cup value £10 for the best Dark Brahma in the Show was awarded to this bird. The second, a very rich black-breasted bird with beautiful broad green-black bars, was in excellent condition. Third the same that was third at Bristol; he has a good head, breast slightly ticked with white, and rather long in the back. Fourth a very good bird, but out of condition. Several other birds were noticed in this class. Dark Brahma cockerels had forty-five entries. The class, with the exception of the first-prize bird, was far behind those exhibited last year in quality. The first was Mr. Lingwood's beautiful-headed bird that won first at both Crystal Palace and Bristol. He was very far ahead of any other bird in the class, and ran hard for the £10 cup. The second slightly ticked in the breast, otherwise a good bird. Third evidently a very young bird, and rather weak in legs, large, good in colour, and likely to make a grand bird. Fourth another late-hatched bird, beautiful in colour and neat comb, but at present looks rather leggy. Fifth a grand bird that has won at several shows, now getting a little loose in condition, especially in his wings. Dark Brahma hens, thirty-seven entries. The first is beautifully pencilled throughout, but slightly twisted in hackle; her ground colour for a hen is very clear and beautiful. Second a far better shaped bird and well pencilled, but not so even in marking as the first or so good in ground colour. Third large bird, good in shape. Fourth beautiful in marking and shape, but red in ground and rather hooked. Several other good hens received notice; Messrs. Newham & Mauby had a beauty, but she was too high in the back. Dark Brahma pullets were a large class of fifty-four entries. The first was the Oxford, Crystal Palace, and Bristol first-prize bird; in beauty and evenness of pencilling she is grand, and her ground colour is exceedingly clear. She is also well feathered, and her pencilling all alike, from her neck to the tail, and from her throat to the end of her

feet-feathering. The second was from the same yard, and quite as clear in ground colour, very equally pencilled, the pencilling a little broader than the first, and to all appearance a younger bird. The third was also well pencilled, but not quite so clear in ground colour. Fourth a little too light in front. Several other well-pencilled pullets were exhibited in this class, but in many the ground colour was too brown. The class as a whole was much better than the cockerels. Light Brahma cocks had twenty-two entries. The first and £10 cup for the best Light Brahma in the Show went to Mr. Horsfall's grand Palace and Bristol winner; he is a massive bird and won easily. The second is also a good-coloured bird; the third and fourth are also good. The class was far better than the cockerels. Light Brahma cockerels was a large class of fifty-one entries. The first a large bird, good in colour and well feathered; he has all the appearance of making a first-rate old bird. Second has won at several shows, and is a grand bird, but here had a curiously twisted hackle. Third a large fairly coloured bird and well feathered, but he has got his hackles quite if not worse than the second, apparently with being over-exhibited. Fourth a fine bird, but not good enough in colour. Fifth a very pretty bird in all respects, but rather small. Light Brahma hens were a splendid class of thirty-two entries. The first, second, and third were very equal and first-rate in quality; the fourth a large beautiful-coloured bird, but rather too leggy. The Light Brahma pullets were a beautiful class of fifty-seven entries. The first had a beautifully marked hackle, very deep yellow legs well feathered; she was in grand condition. Second was also a great beauty, good in shape, well-marked hackle, and clear in white. The third was a large bird, very pure in white, and well feathered. Fourth very pure in white, with good well-feathered legs and feet, well marked in neck; she appears young and likely to make a good bird. Many other birds were noticed in this class, which was a very good one. The Brahma Selling class for cocks were only a medium lot; the first were Dark, second Light, and third Dark. The Selling class for hens was much better than the cocks, and some cheap bargains were held out here; no doubt the prize birds would run up at the auction.

**DORKINGS.**—The falling-off in Coloured Dorkings is astonishing; we know of five eminent breeders possessed of splendid chickens, who contented themselves with the laurels of Oxford, the Crystal Palace, and Bristol. The first two cocks were ahead of the rest in size, and good Dorkings in shape; third a well-shaped bird with a poor small comb and bow legs. The cockerels numbered twenty-six; we remember 75 at Birmingham! they were a poor lot; certainly but one, if one, would have been in the Palace list. First a long-legged bird, fair all round, dark in colour; second a smaller and lighter bird with suspicious marks as if he had had sprigs on his comb; third much better in shape, but a bad Silver-Grey in colour; fourth a dark bird, very brown on wing, his comb ugly and tilted forwards; fifth too long on leg and chicken-like, but much the best of the prize birds. We should certainly have put Mr. Walker's commended bird first or nowhere; he looked very antique for a bird of the year. Mr. Baker's highly commended bird was a very fair one with a bad comb. Hens were a better class; first, a splendid bird a little long on leg; second, a long bird with a rich brown breast, a little dark in feet; third, a good well-shaped bird. 447 (Mrs. Arkwright), good in form and white in feet, nearly black in colour. Pullets were poor; first a bird very like her owner's second-prize hen, sooty in feet; second, square and good, with a most matronly look; third a fair-size bird, good in shape and colour, and a veritable pullet. We should have put her first. 463 (Dr. Snell) seemed ill. The arrangement of baskets is such (they are packed closely in a subterranean limbo) that it is impossible to get one out, and so sick birds cannot be sent home.

**Silver-Greys.**—The only really good bird in the cock class was Mr. Cresswell's Bristol cup-winner. He was put into a broken pen, fought all night with his neighbour, and was in a sorry plight when the Judge came round. The same thing happened to one of Mr. Matthew's Game cocks. It is positively shameful that an entrance fee of 8s. cannot command the use of a pen such as could be bought for 5s. The first-prize cock was a very poor bird, with no distinct fifth claw on one foot; second fair in shape, but orange-coloured on the wing. Cockerels were much better. Ten out of the twenty shown were claimed on the first day, among them Mr. Cresswell's unnoticed bird for fifteen guineas. First a fine upstanding bird, with good comb and feet, a little yellow in hackle, and spurs inclined backwards; second good in comb, but very dark in feet; third a pretty smart little bird, which found a purchaser at the auction; 485 (Burnell) a grand bird, but his comb is going over; 488 (Cunningham) a pretty bird. Hens were few; first a beautiful bird, the Palace cup-winner; second brown and indifferent. We much preferred the Bristol winner. The first pullet was a pretty little bird, which must have won from her bright condition; her feet are very dark. Second too narrow, but exquisite in colour; 500 (Mrs. Colville) a nice bird, with a bad toe; 504 (Burnell) large, but not looking her best.

Whites are always good classes here, from the Show being the only one where chickens and adults both have classes. The first cock was well ahead; he has a large and good comb, but swollen feet. Second a fair bird all round; we should have put Mr. Boissier's highly-commended bird in his place. Lord Sudeley was fortunate in getting a highly commended for a bird with terrible feet. The cup cockerel is certainly an immense and massive bird, but rather sunburnt. We almost prefer Mrs. Hayne's second-prize bird, the Palace winner. In the class for hens Mr. Cresswell's Palace cup bird was in our opinion much the best, though the cup hen is a square fine Dorking; second was very poor and a mistake. The pullet class contained several fine birds. The first bird was very pretty and good in comb; second good in shape but yellow. We thought Mrs. Hayne's as good as any. The Selling classes were a more rubbishy lot than usual.

**COCHINS** were throughout good classes. As we have said, we attribute this to the hardness of the breed, and the consequent confidence with which their owners hazard the dangers of Birmingham.

The first Buff cock was a fine upstanding bird, short on leg, very bright and even in colour, with good though rather stiff leg-feathering. Second longer in leg and lighter in colour. He was shabby on legs and down in tail, and we did not like the award. Third as good as any; a little white on tail. Fourth a very nice bird with buff tail; not quite so uniform in colour as some, but capital in shape. We must say that in spite of his not looking very bright we should have put Mr. Burnell's grand old highly-commended bird high in the list. Cockerels were a fine class. First Mrs. Tindal's beautiful bird, not looking at all as he did at the Palace; his comb went over terribly with the warmth of the Show. Second a well-shaped bird, inclined to canary colour. In most ways he took our fancy much, though far too pale on the back. Third not large, but a very nice bird; fourth large, rather dark; fifth disfigured by white earlobes and a black tail. In hens Mr. Procter's splendid bird was first-and-cup. She is of a very even pale buff throughout. Second a fine hen all round; not equal to the first in size. Her colour is medium, her comb too high. Third large, fine in shape, and feathering; a little ticked in neck hackle. Fourth we believe the first Palace bird. Her comb is very shabby and her legs long, and we did not think the award a good one. Beyond the prize birds there were several nice hens. 649 (Fowler) bad in comb, but very good in colour; 645 (Darby) good all round; 661 (Tomlinson) small and good in colour; 663 (Ryland) very fair. The class was a very strong one. The first pullet was good in size with fine high fluff; she might have a little more shank-feathering; her colour is of medium darkness. Second a good pullet throughout; a little long in back. Third smaller but shorter in back; her shape fair, her colour a little dead. Fourth small, but bright in colour. Fifth large and well shaped, with bright neck hackle, but back colour not very sound. We could not imagine why a beautiful pullet of Lady Gwydyr's (669) was not among the winners. 677 (Tomlinson) a fine pullet, a little high on leg and with twisted hackle; 683 (Gwynn) bright in colour with hardly any leg-feathering; 684 (Procter) worthy of notice; 687 (Burnell) good.

**Partridge.**—Cocks were a splendid class, the cup bird was in colour far ahead of all the rest; his shape and comb are capital, his foot-feathering a little broken. When we saw him on the second day of the Show he seemed suffering much from a terrible draught which rushes in from the great hall into the heated annex. Second, as well as the cup bird, short-legged, a broad and massive bird, darker in hackle than the first; his foot-feathering is singularly fine for a bird not hocked. Third a taller bird than the other two winners, very dark in neck-marking; 704 (Tudman), capital in shape but a little white in tail, and a little tinged in fluff; 707 (Tomlinson), wonderful in breadth. The cockerels were not so even a class; the winners being very good, but several very poor birds in the class. First a marvellous bird in size, he would quite compete with the adult cocks; his comb is high and weak, and may, we would fear, go over. Second, another very fine bird, better in comb and running the first hard. Third not so large; a darker bird in hackle, with good black fluff but scanty leg-feathering. Hens.—The cup went to a beautifully pencilled hen, fair in size. Second quite as good in shape, but not in condition and marking. Third, small and well shaped, with breast prettily marked. The class was not a remarkable one. The first pullet was marvellous in marking, like a very well pencilled Dark Brahma; her comb is too high and her shape only fair. Second a grand pullet in size and shape, but deficient in marking; she was next to the cup hen, and certainly looked as large. Mr. Burnell's very highly commended pullet was prettily marked.

Whites were good classes all round. The cup cock was a magnificent bird, his feathering very heavy. His back does not rise towards the tail quite to our fancy. He is the bird that was so unaccountably left out of the Crystal Palace list. Second long on leg and stilty. Third much smaller, but well shaped and well feathered, a very pretty cock. We liked Mrs. Tindal's bird; Mr. Boissier's too, the Palace cup bird, we thought worthy

of a notice, though he is apparently a little overdone. 768 (Tomlinson), not good in colour, but nice shape. Cockerels were not very remarkable, the two first winners being very long on leg. The first bird is very white and has a fair amount of feathering. Second a bird of much the same type. Third, White, but a little rough in wing. Hens were a capital class. First a grand hen, perfect in shape, a little scaly on legs; we think the second quite equal to it. Third was larger than these two, but not nearly so perfect a Cochins in shape. 800 (Warde), a well-shaped hen but hocked and minus tail; 804 (Percival), good but twisted in back. Pullets were hardly so good, several of them being badly shown. First a fine well-shaped bird good in cushion, a little overhocked. Second quite as good in shape and fluff as the first, but not so large. Third an immense bird, too long in leg and back; we preferred 805 (Tomlinson).

*Blacks* continue to improve. The cocks were in a fair light, the hens in a very bad one on the ground; but Mr. Hewitt took immense pains in judging them to see their colour fairly, having them put into baskets in a full light. The first cock is a bird of the year; he certainly is small but well shaped, and with a beautiful green gloss. Second a tall Langshan-like bird with a bad comb; his only merit was his green colour. 825 (Darby) was by far the best shaped and best feathered bird in the class, but some accident has evidently happened to his comb, and his full colour has not yet come out from the moult. We also admired Mr. Storer's highly commended bird. The hens of this variety when shown well are certainly lovely. First was a splendid bird all round, and second also good, but we cannot pretend to criticise their colour in such a wretched position.

*MALAYS* were very good classes and the competition strong, but to our thinking the Judges in making their awards went more for utility and beauty rather than following the old type of the breed. Malays have always been notorious in the public eye for their ugliness, but there is no doubt there is not a more useful fowl for table purposes, whether crossed with the Game or the Dorking, whereby those portions of the bird most esteemed when on the table are best developed. We always thought, however, that extreme development, broad shoulders, high hocks, and vulture neck were the proper characteristics of the breed, and which should be more closely adhered to in the show pen.

*THE FRENCH BREEDS* were better represented than usual, Messrs. Mackwell, Burrell, and Stephens showing some capital *Orpèvres*. *Houdan* cocks were a very meritorious collection, but we cannot say so much for the cockerels, which we thought, as a lot, were not up to the mark.

*SPANISH* were small classes. In old cocks only two put in an appearance, neither of them good in quality. Spanish cockerels, with the exception of the cup bird, the second-prize bird, and one highly commended, were a very poor lot, very different to such as we have seen at this Show. Spanish hens were a very good class, as were Spanish pullets, especially the first and second-prize birds.

*HAMBURGS* for the first time, as we have said, had separate classes for adults and chickens. As a rule Black Hamburg cocks retire into private life after their first year. It may be some slight advantage that they are now able again to be shown, but still with tinged earlobes they do not compare favourably with cockerels. The pens in which the Hamburgs were shown are far too small for any cock of the breed to show himself off properly; but, as if this were not enough, they were made to overlap each other, so that the birds could not stand without scraping their tails against the wire. Black cocks were not grand; the merits of the cup cockerel were good carriage and a good spike to his comb, his earlobes were puffed and his tail almost devoid of side feathers. Second was a beautiful bird in carriage. Among the highly commended birds were some very nice cockerels, 1126 and 1134 (Serjeantson), 1128 (Stott & Booth), 1131 (Pickup). We did not like the first hen, and many people thought her a pullet; her tail is far too broad. Second was a pretty bird in head. The first pullet had a pretty but rather heavy comb and a good head; second far too purple tinge. The awards in these classes did not seem to satisfy the fanciers of the breed, the Judge having apparently paid more attention to the heads of the birds than to their colour. The first Golden-pencilled cock was very good, particularly even in colour all over, and sound on breast, and his tail well laced; we should have given him the cup before the cockerel. The latter had a neat and pretty comb, but his tail was almost barred. Second cockerel had not much style, but a honest comb. The first hen was good all round, with medium breadth of barring, capital in tail. We much liked the second hen for her fine, small, distinct barring, though, as is generally the case with such birds, her hackle is not clear. The first pullet was much the same type of bird, rich in ground colour and a beauty; second a nice bird, but not so good in wing or tail. Only one cock put in an appearance in the class for Silver-pencils, a fair bird, with only an attempt at tail-lacing, and comb too shiny. The cup cockerel had a pretty tail and a manifestly improved comb; the second cockerel had not the style of the first, still we should have put

him first for his honest comb; his lobes were a little tinged, but apparently from a fight. The first hen was nicely barred, the second too heavily so. The first pullet was rather patchy on the breast, but otherwise well marked; the second generally equal to her, but bad in comb. The first Silver-spangled cock was good in comb and heavy in spangling; second not his equal in comb or marking. The first cockerel was nice all round. We regret to say that a pin was extracted from the front of his comb; we forbear from commenting upon this horrid piece of cruelty, for various circumstances incline us to believe that it was not put there by the exhibitor. The authorities were most courteous in showing us the place from which it came, and anything more purposeless than placing a pin in such a position, where it could not possibly improve the comb, we cannot imagine. The second cockerel had a narrow comb for a Spangle, pretty sickles, and nice moderate-sized mooning. The hens numbered only three, all good birds; the second-prize birds were very even, the first being best marked on the wing but a little heavy in comb. The first pullet was a beautiful bird, with even mooning, but too heavy for our fancy; second a bird with smaller spangles. In Golden-spangled cocks first was a bird apparently rich in colour and certainly well marked; his tail was broken by the pen. Second had not so good or natural a comb; probably his carriage would be good in a proper pen. The first cockerel was good in hackle and mooning, and magnificent in comb, which we hope was natural; second a nice bird in carriage. We regret that we cannot criticise the classes for hens of this breed, as we could not succeed in finding them. After the cockerels came a row of empty pens, and then some Bantams. The numbering of pens throughout the Show was purposeless and perplexing; here it defied comprehension.

*POLISH* generally were excellent, and we were glad to see the old White-crested Blacks looking up again. They are now much better than they were a year or two back, but still nothing like the birds which Mr. Edwards used to show some ten years ago. In no class, however, is improvement more noticeable than in the Golden-spangles, which at one time went down to a very low ebb, and it is now not uncommon to see them in exhibitions where the colours compete together carrying off the honours over the Silvers. The first-prize old cock has a large well-shaped crest, and capital colour; he is the Crystal Palace cup-winner, and was shown in fine trim. The young *Golden spangled* cocks were the largest class of Poland in the Show, and contained a number of fine specimens. The first prize went to a bird of excellent colour and crest, but very round-backed. The second (Beldon) is not so good in crest, but will improve considerably when properly through his moult, and we think owing to the defect in the first bird he was entitled to chief honours. Old hens were a good class of six. First the Palace winner, and a more beautiful colour or better marked hen we think we never saw. The second was not far behind her, shown by the Duchess of Hamilton, a new name to us as an exhibitor in the variety. Pullets were also a good class; first attractive in colour but small in crest, but the second was our fancy for pride of place, although we should have preferred No. 1311 (Shepherd) if she had not possessed the same defect as the first cockerel. *Silver-spangles* were as usual the cream of the Polish classes. In cocks Mr. Adkins deservedly took first and cup with a fine old bird, being hardly pressed by Mr. Beldon's grand old crack, but not looking quite in his usual fettle. No. 1316, the property of the Countess of Dartmouth, is a beautiful bird if it were not for a yellow tinge in his feather. We think there was no bird in the Show with a better crest than he has. In cockerels Mr. Adkins was again first and second, but we decidedly preferred his second bird to its more successful *confrère*, being a better bird all through, while the first is rather straggling in crest. We specially admired the Silver-spangled hen with which the Countess of Dartmouth was first. The Silver-spangled pullets only mustered four, but all were good and with little to choose between them.

*SILKIES* had but three entries. Both the winning pens were good, the first best in leg-feathering and justly placed we think; but the second were very elegant in style.

*ANDALUSIANS* were a nice class, the winners well selected in our judgment. The first cock was fine, with a stiff and good comb, and the hen immense for the breed. In the second pen was a very rich-coloured cock, a little white in face.

*LEGHORN*.—A nice pure white pair came in first, a Brown pair second; their colour seemed much brighter than we are accustomed to see in this breed.

*ANY OTHER VARIETY*.—First were a grand pair of La Flèche, second capital Scotch Greys. We should much like to see this hardy breed more known in English farmyards. Third beautiful crested African Guinea Fowls. Some curious and interesting Indian Game were shown by Mr. Montessoro and Mr. Dutton, and some excellent bearded Sultans by Mr. Shaw.

*GAME*.—Among the Game the best classes were the *Brown Red* cocks and cockerels, and the *Brown Red* pullets. The *Black Reds*, however, were better classes than usual. *Duckwing* cocks were fair, but the hens were not equal to former years. The

Blacks were inferior as a class, their greatest failing being dark eyes. Pile cocks were only a moderate lot, but the hens were better.

**BANTAMS.**—There were very few first-class birds among the Game Bantams, it being difficult to find a really superior specimen among the *Black Reds*; the best, however, were those belonging to Messrs. Morris, Fletcher, and Addie. In the other Game classes, however, Mr. Fletcher's *Brown Reds* and Mr. Brownlie's *Piles* stood very prominent in their various classes. All the other classes except Game were marvellously good, and the *Seabrights* held their own for beauty against all new comers, and were well represented. We were glad to see the *Silver-laced* assuming the pure frosted-silver ground colour for which twenty-five years ago they were so notorious. The *Golden-laced* were also remarkably good, with those peculiar traits of character which mark this distinct breed (hen tails and hackle), exceedingly well developed in the cocks, a feature which had unadvisedly been lost sight of for many years past. *Blacks* were very good, though limited in numbers. In the first-prize pen of *Whites* were such as we have not seen at any show for some years past. They were simply grand. In the Any other variety classes the first prize went to light-coloured *Japanese*, and second to *White-booted*. A pen of extraordinary *Friszeled* fowls of remarkable quality were also shown in this class, but the hen had the fatal objection of being Dorking-toed. We also noticed several pens of *Cuckoos* of highly meritorious character. In the *Selling class* for Bantams the first were a good pen of *Light Japanese*; second also good *Blacks*, and the third *Duck-wing Game*. This was a very good class, comprising several capital pens of the leading varieties, many of which were not long in finding customers.

**DUCKS.**—*Black East Indian*.—This is one of the classes which tries the mettle of a judge, perhaps more than any other variety which can be placed before him to adjudicate upon, and we were glad to see in this instance Mr. Hewitt had every bird out and examined in hand, although the class was an extensive one, and the result was that the first and second prizes followed in the same groove as at the late principal shows, the third going to a new comer; but a more equal quality throughout the whole classes perhaps never existed.

**DUCKS OR ORNAMENTAL WATERFOWL.**—Five pens of *Mandarin*s were shown in the class expressly for that breed, and certainly never before were five pens of so perfect and lovely conditioned birds seen side by side. The first prize went to a pen which were admired by almost every visitor to the Show. *Carolinas*, for which also there was a special class, were scarcely less remarkable for beauty and condition. *Call Ducks* (open to White or Grey), only two pens were exhibited, both Grey, and by the same exhibitor; but we never remember seeing any so good since the time of Harvey, Dutton, and Bailey, who exhibited some ten or twelve years back. The most fastidious could not find fault with them.

**DUCKS OR ORNAMENTAL WATERFOWL**, which is a class open to any variety of Waterfowls for ornamental purposes was a very large one. The first prize going to Pekins, remarkable for their excellence. We believe these are the coming Ducks for utility, and will eventually beat the Rouens and the Aylesburys. A better pen than Mr. Fowler of Aylesbury showed has never been exhibited. They were, however, closely followed by a pen from Mrs. Troughton, which were very highly commended. The second prize went to *Whistling Ducks* of the autumnal variety. And half a dozen extra prizes might with perfect justice and the greatest ease have been apportioned in this class.

#### PIGEONS.

Several alterations have been made in the Pigeon classes, the principal of which has been to raise the first prizes throughout from 30s. to £2 again—a very commendable alteration. The third prizes, however, have been abolished in all the Pouter classes, Short and Long-faced Tumblers, Barbs and Trumpeters, as well as one of the first prizes in the new Variety class. Exhibitors in those classes cannot grumble at this alteration, for the entries therein have always been very small, and we have not the slightest doubt but when the classes are better supported the old state of things will be restored. Among the other alterations is the abolishment of the guinea subscription, which has hitherto deterred many fanciers from exhibiting, but who are now enabled to send two or three pens at a fair and proportionate charge to the amount offered by the Society for competition. Many a time have we along with others advocated the propriety of this alteration, but hitherto all efforts have been unavailing, and we cordially welcome the spirit which now seems to prevail the poultry Committee, and hope it will meet with a suitable response from the fancy generally. The previous announcement of the Judges' names was another instance of their desire to comply with the spirit of the times. But we should very much like to know also how the work is to be apportioned. New classes were this year opened for young Dragons, Dragon hens, young Antwerps, and Antwerp hens, and towards the additional money thus offered a few members of the Birmingham Columbarian Society who are interested in the varie-

ties specified contributed ten guineas. The care of the birds was again placed in the skilful hands of that old and experienced fancier, Mr. J. W. Edge, who seems never to tire in looking after his charges. Whenever and wherever we looked into the pens the evidences of cleanliness and comfort were always to be seen. We should only like to see Mr. Edge's services brought more generally into requisition. One alteration we should very much like to see, and that is the abolishment of the Pigeon pens altogether, and an entirely new and more modern set substituted. By this means the Society might double the space at their disposal, and the birds would be better seen and better judged, for we feel sure this is the principal cause of some of the errors of judgment which took place at Bingley Hall last week. The birds ran into the dark corners of some of the pens, and by no amount of poking or exertion of any kind would they allow themselves to be fairly inspected. We are glad to see the point out done away with this year. The total entries are 669, against 541 last year, and the quality throughout is the best which has been seen in Bingley Hall for some years.

**CARRIERS** generally were a great improvement on the Bingley Hall Show of the last year or two, the general quality being far more uniform. Old Black cocks mustered seven, the cup for the old birds going to Mr. Maynard's Crystal Palace cup-winner. He is one of the best birds for head properties we ever saw, and if he could only be provided with a new body to match he would be a wonder indeed. The second (Fulton) is a bird of high quality in all but the beak-wattle. Third (Siddons), very large and good quality of eye, wonderfully narrow skull, and a good colour, but rather fine in wattle. The class generally was a good one, and the prize birds we thought rightly placed. In Black hens we specially admired the one with which Mr. Fulton stood first. A little small she certainly was, but in other points to our mind she was a model Carrier. Why the second bird received her honours we could not understand, for she seemed to have no particular property to recommend her; she was out of condition and had a lump on her wing. Third was Mr. Maynard's old hen, a bird of good shape. We should have preferred to either of these Mr. Yardley's highly commended bird 2042, which is possessed of many excellent properties. **Dun cocks.**—First a good bird, but wants a little more neck; capital in eye and wattle, but a little down-faced. Second not so good in beak-wattle as first and rather wide at back of skull, but a good colour. **Dun hens.**—The class fairly good. First a good colour and deserves her position, but is not quite perfect. Second also a very nice hen, but we question whether she will ever make up. In Carriers, any colour, we thought Messrs. Stretch's second-prize bird ought to have been first. Black Carriers hatched in 1876 was an excellent class, but we thought Mr. Maynard was very lucky in carrying off the cup. It was the general opinion that this class was not well judged and the best birds were unnoticed. We think first and second might have been found in 2065 (Mrs. Hallam), the first Peterborough and second Bristol bird, and 2068 (Fulton), a fine racy fellow, but wanting a little more eye. We should not have minded Mr. Maynard's third-prize retaining its position, which was a very stylish bird and a hen. Two or three unmistakeably old birds were shown here. Carriers, any colour, hatched in 1876, only mustered eight, and those mostly Duns and not superior. We liked 2086 (Kempton), a highly commended. The general opinion was that he is not a this-year's bird, but on close examination we thought he was really a young bird and ought to have been first. We did not care for any of the other birds.

**POUTERS** as a whole were the best lot which has been in Bingley Hall for some time. The classes were not so large as at the Palace, but the quality was well represented. The Blacks, both cocks and hens, were generally the best. In Red or Yellow cocks Mr. Pratt was first with a bird of this season, but we preferred the second to him, and would have given second to either 2095 (Gresham) or 2097 (Fulton), both of which were better birds. **Red or Yellow hens.**—The first (Gresham), a Red, thoroughly deserved her honours, being a good colour and a very showy bird. Second we would have passed, as she was more fit for a breeding loft, being too thick, heavy, and coarse for the show pen. The prize in our opinion ought to have gone to Mr. Pratt's Yellow (2099), which was only commended. **Blue cocks.**—The cup bird (Fulton), a fine long slender bird with beautiful limbs. Second again, we should say, was a hen also wrongly placed, and we preferred 2106 (Watkin), to him. **Blue hens.**—First a showy bird, and first also at the Palace. Second rather thick in girth, and nearly swallow-throated. **White cocks.**—The first prize should have gone to 2119 (Pratt) highly commended, which was by far the best bird, possessing a fine globular crop. Second very fortunate to gain his position, being short in limb and thick in girth. We preferred 2116 (Fulton) for second, although he is rather heavy in limb. **White hens.**—First a magnificent bird belonging to Mrs. Ladd. Although we did not quite like the second bird, she was no doubt in her right position; 2124 (Gresham) was a good bird, but somewhat coarse. The Any other colour classes were all Blacks, and an excellent lot they were. First (Pratt), the best coloured and marked bird in the

who, J. Cook, E. Kendrick, jun., F. E. Richardson, J. Rigg, H. J. Gunnell, J. Everett, C. Edwards. *Cockerels*.—Cup, F. Lythall. 2 and 3, W. Wykes. *Hens*.—2, W. Wykes. 3, W. Walker. 5, E. **JUDGES**.—*Poultry*: Mr. J. Baily, Mount Street, Grosvenor Square, London; Mr. J. Dixon, Clayton, Bradford; Mr. E. Hewitt, Sparkbrook, Birmingham; Mr. W. R. Lane, New Street, Birmingham; Mr. J. H. Smith, Skelton Grange, York, and Mr. R. Teabay, Fulwood, Preston. *Pigeons*: Mr. T. J. Charlton, Bradford; Mr. F. Esquilant, Brixton, London; Mr. G. Jordin, Birmingham, and Mr. Harrison Weir, Staplehurst.

## KINGSTON-ON-THAMES POULTRY SHOW.

Thus Exhibition was held in the Drill Hall, a place admirably adapted for a good show. The schedule was very imperfect, and some confusion occurred with the pens on the opening day, and we believe the Judges (Messrs. Teabay and P. H. Jones) had the greatest trouble to find the classes and make their awards, which, however, were very satisfactorily accomplished; still the Secretary, who was ready to put crooked matters right as far as he could, was courteous and indefatigable in his work, and we hope this suburban Show may, under judicious management, flourish in future.

*Dorkings*, Coloured, came first on the list, and a very good pair of adults were first, both white in feet and large. In the next class a well-shown pair of Whites came in first, and very deservedly. *Cochins* made but small classes, but the quality was good; the first in each class being really superior specimens. In *Brahmas* the first Darks were only moderate; entered in the catalogue or £5, which should have been £50. In the hocked class a very large *Brahma* won the cup. In *Polands* a very good pair of White-crested Black chickens came first. In *lays* the first and second were both good pairs of Dark birds in good feather, and the third were lustrous Blacks. The *French* were good. The first *Houdans* a good pen, as were the first *Crèves*. In *Leghorns* the Whites were the best, all being fairly good in colour, and the first and second winning by their better plumage; the third being very young but most promising chickens. *Minorcas* were a very small lot; the first very lustrous Blacks, and neat in combs.

*Bantams* made excellent classes. The first Laced were a good pair of Silvers, not quite neat enough in comb, but very well marked and clear in colour; while in the Variety class moderate Black Rosecombs were first, and Brown Frizzles with non-matching legs second, third again going to Blacks. *Spaniards* were excellent, the first pair very good indeed; the cock really wonderfully good. The Selling classes were good; the prohibitory price being £5 5s. per pen brought a good lot of birds. In single cocks of the first-named breeds a Dark *Brahma* was first, and a capital pair of hens of the same breed also first in the hen class, while in the other classes we saw a capital pair of Spanish pullets and some extremely good *Crèves* from Mr. Harley. We had almost

omitted the *Game* classes and the *Hamburgs*. In the former among the Black-breasted Reds the first were in good feather, and the cock capital in head and of good carriage; the second too were in very hard feather, and the hen we especially liked. *Duckwings* were only moderate, save the first-prize pair, which were of good colour, and the cockerel stylish. In the variety *Game* class a very good pen of Piles easily came in first. They were of good colour, and the cock capital in head. The third prize was, we believe, withheld. The *Hamburgs* again made but small classes. The Golden-pencilled were, perhaps, the best. Both first and second pairs were in good condition. In *Spaniards* a good pen of Silvers won first. Blacks had but four pens, and the awards seemed quite correct. The first were neat in combs, and the cock had a good tail.

The *Pigeon* department was very limited; but here the pens were mixed up in so bewildering a manner that we really could not make them out at all. We give the list of awards as near as we could obtain them.—W.

**POULTRY**.—*DORKINGS*.—Coloured.—1, Rev. R. S. Woodgate. 2, — Bonsey. 3, — Brown. *Any other variety*.—1, Miss D. Mackenzie. 2, R. A. Baker. *COCHINS*.—Partridge.—1, C. Marshall. 2, Mrs. Radcliffe. *Cinnamon and Buff*.—1, A. Darby. 2, Mrs. A. T. Tritton. *Any other variety*.—1, A. Darby. 2, R. A. Boissier. 3, Rev. R. S. Woodgate. *Black*.—1, A. Darby. 2, Rev. J. D. Peake. 3, A. Kitchen. *BRAHMAS*.—Dark.—1, H. Stephens. 2, Mrs. Radcliffe. 3, Rev. J. W. Joyce. *Light*.—2, W. Wells. 3, G. W. Messenger. 3, W. S. Smith. *GOSLINGS*.—1, Miss Radcliffe. 2, T. Baker. 3, W. S. Smith. *TURKEYS*.—1, F. Ward. 2, G. H. Langford. 3, Countess of Lovelace. *POULTS*.—1, F. Ward. 2, J. H. Webber. 3, Countess of Lovelace. *who*, Mrs. Radcliffe. **SELLING CLASS**.—1, G. Ellis. 2, T. W. Anns. *who*, Rev. J. D. Peake.

**PIGEONS**.—*ANY VARIETY*.—1, 2, and 4, O. E. Cresswell. 3, R. Wilkinson. 5, T. Randall & Son. 6, B. White. 7, A. F. Skinner. *who*, J. R. Capron, J. Chuter.

## CARMARTHEN POULTRY SHOW.

This was held on the 12th inst., and though the entries were not large the Show was an excellent one, and the birds came from many celebrated yards. Mr. John Martin awarded the prizes to the great satisfaction of all. The Exhibition was held in the Market Place, and the Society's own pens were used.

*Dorkings* made a fair display, and the first and second *Spanish* were shown in capital trim, the first cock's face being very good in quality and large. In *Cochins* some good Partridges were shown, and though all varieties competed together first and second prizes went to birds of good quality of this variety. *Light Brahmas* were not nearly so good as the Darks, in the latter breed the prize birds being excellent in size and the hens well pencilled. *Game* were admirable. The cup went to a grand pen of Brown Reds; the cock of wonderful excellence;

the hen, too, good in head and fine in tail. *Polands* were well represented. In birds of any age capital *Silvers* won first, while in Golden chickens a smart pen were first, very fair in crest, and bright in colour. Mr. Burrell's two pens were both empty. *Houdans* only made half a dozen pens. The first-prize birds were well selected and prettily marked. In the Variety class *Malays* won first and second, the first being good chickens in fine condition. Brown *Leghorns* only appeared. A capital pen took first, good in tails and neat in comb. In Game *Bantams* a very smart pen of Brown Reds won first. In the Variety Bantam class Blacks were first, second, and third.

The *Pigeons* did not muster very strongly. Of the various classes *Dragoons*, *Fantails*, *Jacobins*, *Turbits*, and *Owls* were the best. In *Jacobins* a good pen of Blacks won first, Reds taking second and third. We saw, too, lustrous *Archangels* in the Variety class. This breed seems to be looking up, for at Birmingham, Guildford, and Kingston they have appeared in good numbers and of excellent quality. *Barbs* and *Antwerps* had a class together; they made eighteen pens, in which a good pen of *Barbs* came in first, and Red-chequered *Antwerps* took second. *Pouters* had no entries.

POULTRY.—*DORKINGS*.—1, W. Bevan. 2, H. Feast. 3, T. Harries. *SPANISH*.—1 and 2, J. W. Holden. 3, A. J. Radford. *BRAHMAS*.—*Dark*.—1, H. Feast. 2, J. S. Maggs. *BRAHMAS*.—*Dark*.—1, H. Feast. 2, J. S. Maggs. 3, A. H. Robbins. *Light*.—1, H. Feast. 2, E. Lawrence. 3, C. Chitt. *CHINA*.—1, D. Lewis. 2, W. Kent. 3, H. Feast. *GAMMA*.—*Black-breasted Red*.—1 and 2, J. P. James. 3, D. Morgan. *Any other colour*.—*Emp*. R. Pearson. 2, J. P. James. 3, M. Woosham. *Untrimmed or Undubbed*.—*Cock*.—1, J. Cock. 2, D. Morgan. 3, W. H. Taylor. *HAMBURG*.—*Golden-pencilled*.—1, J. Carr. 2, H. Feast. 3, C. E. Senior. *Silver-pencilled*.—1, H. Feast. 2 and 3, W. F. Maynard. *Golden-pencilled*.—1, H. Feast. 2 and 3, M. Langdon. *Silver-pencilled or Black*.—1, H. Feast. 2, D. Morgan. 3, L. O. Lewis. *Polands*.—1, J. Hinton. 2, H. Feast. 3, S. W. Thomas. *Golden*.—*Chickens*.—1, J. J. Scott. 2, D. Lewis. 3, A. Fry. *FRENCH*.—*Houdans*.—1 and 2, S. W. Thomas. 3, J. J. Scott. *FRENCH OR MALAYS*.—*Any other variety*.—1, M. J. H. Spurry. 2, H. Feast. 3, J. Hinton. *LEGHORN*.—1 and 2, F. L. Green. 3, S. L. Bradbury. *BROWN*.—1, J. Heastie. 2, E. W. Pickard. 3, F. L. Green. *BANTAMS*.—*Game*.—1, G. Lewis. 2, A. J. Radford. 3, H. Feast. *Any other variety*.—1 and 2, H. Feast. 3, T. H. Phelps. *ANY OTHER BREED OR CROSS*.—1, H. Feast. 2, T. F. Phelps. *SHILLING CLASS*.—*Medal*, D. Lewis.

POULTRY (Local Prizes).—*DORKINGS*.—1 and 2, H. Feast. 3, J. Harries. *BRAHMAS*.—1 and 2, H. Feast. *COCHIN-CHINA OR SPANISH*.—1, H. Feast. 2, D. Lewis. *HAMBURG*.—1, H. Feast. 2, D. Lewis. *GAMMA*.—1, D. Morgan. 2, H. Feast. *FRENCH*.—1 and 2, H. Feast. *BANTAMS*.—1, H. Peerman. 2, G. Hughes. *ANY OTHER BREED*.—1, J. H. Spurry. 2, D. Lewis. *DOCKS*.—*Aylesbury*.—1, J. Buckley. 2, J. Buckley, Jun. 3, Mrs. W. James. *Any other variety*.—1 and 2, H. Feast. 3, H. Law. *Any Breed, open to the county*.—1 and 2, H. Feast. *TURKEYS*.—1, Mrs. W. James. 2, J. Buckley. 3, L. Williams. *Geese*.—*Toulouse*.—1 and 2, Davies. 3, J. Buckley. *Any other variety*.—1, J. Buckley. 2, W. W. Prosser. 3, T. Fradette.

PIGEONS.—*CARRIERS*.—1 and 2, T. F. Phelps. 3, E. T. Houle. *DRAGONS*.—1, G. S. Prentice. 2, T. Wheeler. 3, E. T. Houle. *TUMBLERS*.—1, E. Lewis. 2, Dr. Morrison. 3, R. C. Carver. *FANTAILS*.—1, T. Phelps. 2, E. T. Houle. 3, G. S. Prentice. *ANY OTHER VARIETY*.—1, E. T. Houle. 2, W. F. Maynard. 3, T. F. Phelps.

RABBITS.—*LOP-EAR*.—1, H. Law. *ANY OTHER VARIETY*.—1, Master V. Thomas. 2, L. H. Law.

### DUNSE SHOW OF POULTRY, &c.

The first Show was held at Dunse in the Corn Exchange on the 14th inst. We must defer our remarks until next week. The following is a list of the awards:—

POULTRY.—*DORKINGS*.—1, G. Ames. 2, Rev. G. R. Cooke. 3, J. Young. *COCHINS*.—1, T. Boyd. 2, S. Logan. 3, Lady Majoribanks. *BRAHMAS*.—1, Hon. R. B. Hamilton. 2, W. Brunton. 3, S. Logan. *GAMMA*.—1, A. Graham. 2, W. McKay. *SPANISH*.—1, J. C. Turnbull. 2, R. F. Scott. 3, Mrs. Logan. *HAMBURG*.—*Golden-pencilled*.—1, W. R. Park. 2, W. Linton. 3, A. Hutton. *Silver-pencilled*.—1, W. R. Park. 2, R. Holmes. *Silver-pencilled*.—1, A. G. Lindsay. 2, S. Logan. *BANTAMS*.—1, R. Johnston. 2, J. Archibald. 3, C. Lugton. *Any variety*.—1 and 2, A. Graham. 3, J. Archibald. *etc.* A. Hutton. A. G. Lindsay. *FARMYARD FOWL*.—1, W. R. Park. 2, J. H. Pitt. 3, W. McKay. *DOCKS*.—*Aylesbury*.—1, Dr. Campbell. 2, J. H. Pitt. 3, Mrs. Logan. *etc.* J. Purves. *Rouen*.—1, S. Logan. 2, A. Campbell. 3, R. B. Kellie. *Any variety*.—1 and 2, Lady Miller. 3, N. Slight. *TURKEYS*.—1 and *etc.* J. Purves. 3, Lady Miller. 3, A. Hewitt. *Geese*.—1, Mrs. Brydon. 2, Lady Majoribanks. 3, Mrs. Dods. *CROSS*.—1, W. Linton. 2, W. R. Park. *HOUDANS*.—1, Mrs. Falconer. 2, G. Walker. *ANY OTHER VARIETY*.—1, Lady Majoribanks.

PIGEONS.—*TUMBLERS*.—1 and 2, W. Brydon. *FANTAILS*.—1, C. McWatt. 2, Lady Miller. 3, G. Patterson. *POUTERS*.—1, A. Graham. 2, W. Patterson. 3, W. Graham. *JACOBI*.—1 and 2, W. Brydon. 3, J. Renwick. *etc.* W. McKay. *NUNS*.—1, W. Brydon. 2, W. Mein. *OWLS*.—*English*.—1, J. Renwick. 2, W. Brydon. 3, W. Renwick. *TURBITS*.—1, J. Renwick. 2, W. Renwick. 3, W. McKay. *ANY OTHER VARIETY*.—1, W. McKay. 2, W. Brydon. 3, W. Renwick. *etc.* J. Renwick.

JUDGE.—Mr. E. Hutton, Pudsey, Leeds.

THE MARGATE POULTRY SHOW.—In our pages will be found an advertisement that the Show at Margate is to be open to the whole county of Kent. When first advertised this Show was announced as being limited to the eastern division of the county, but so unexpected is the amount of support offered by the public that the Committee have resolved to make it a county show; and as the Hall-by-the-Sea, which adjoins the railway station at Margate, has been secured for the purpose, and twelve silver cups and about £110 offered in money prizes, we think the Show deserves to be a great success.

### OUR LETTER BOX.

PROMOTING GRASS ON LAWN (*Inquirer*).—As your fowls have cropped it close, you may make them in return promote the growth of the grass by spreading thinly over it their dung dropped in the fowl house.

BRAHMAS (*Constant Reader*).—You cannot depend at this season of the year on one cock being sufficient for twenty hens. You might in May or June. Give to the Brahma cock and the ten pure pullets the whole of the run. Their eggs will then be saleable and pure. Put the other pullets in the best and roomiest confinement you have. We do not see how another cock will help you in the matter, because you will always be liable to sell half instead of pure birds. The colour of the egg is not to be depended upon, as many of the half-breeds would be dark enough to pass as Brahmas. The confined hens will be better satisfied with a cock, but any bird will do. It is not absolutely necessary. You may remove the lump from the foot of the Houdan and then use caustic. The foot must afterwards be tied up in leather, and the fowl put where it will walk on something soft, as hay or grass. As the wound will be between the toes and not on the ball of the foot, it should not be long in healing.

PULLER'S EYE INFLAMED (*W. H. W.*).—Rub the eyelid with citrine ointment. It is sold by all chemists.

CANARIES—THE LOSS OF EYESIGHT (*A Constant Reader*).—Your general treatment appears to be good, and should not be the cause of your birds losing their sight. In your bird-room a damp one, or do you allow a strong current of air to be passing through it? If so, encouragement will be given to colds, the common precursor of asthma and consumption, and other inflammatory attacks, ophthalmia included. Rooms in which numerous birds are kept should be effectually ventilated, especially during the breeding season, but not in the manner some adopt—namely, by throwing open both door and window, and endangering the lives or constitutions of their birds through their being placed in a current of air. Ventilators should be placed in the uppermost parts of the room, as near the ceiling as possible. Disease is often brought on through impure air, and we know of instances of several Canaries losing their eyesight through the fumes of burning brimstone arising from the periodical stoving of straw bonnets in the house of a bird-breeder whose better-half was a straw-bonnet maker. The birds were of the Belgium breed, and the mischief to them continued for some time before the cause of blindness was found out. Instances of the loss of sight will sometimes occur through the pugnacious tendency of some of the occupants of an aviary, especially over the seed drawer, when the birds have been kept short of their rations. No doubt birds are as liable to cataracts as other animals, and it is just possible your birds may be suffering from the disease; but to arrive at the true cause of blindness in the absence of more than the bare fact is more than we can account for. Remove from the cage or aviary all healthy birds, letting the blind occupants remain together owing to their being familiar with the feeding troughs. At any time it is unwise to permit healthy birds to tenant the same places as those diseased, for infection is liable to be imparted (and it may have happened in your case) through the habit birds possess of rubbing their beaks and sides of their heads on the perches, especially when irritated about their eyelids. Keep the cages clean, and now and then wash the perches. To the asthmatical members give a drop or two of cod-liver oil twice or thrice a week, with a little of the bread-and-milk diet, and a few groats occasionally.

### METEOROLOGICAL OBSERVATIONS.

### REMARKS.

18th.—A very slight frost and white fog; very bright at times in the early part of the day.  
14th.—Dull but without rain; air rather drier at night.  
15th.—Hazy and dull all day.  
16th.—White fog early; rain in forenoon and damp all day; rather clearer at night.  
17th.—Very dull all day, but no rain till the evening; heavy rain in the night.  
18th.—Very damp, dull, and dark all day, except for a short time about noon.  
19th.—White fog, getting darker soon after 9 A.M.; a most miserable day rain in early evening, when the fog was rather less dense. Barometer very low at night.  
Slightly colder than last week; temperature very uniform and no sun. A very gloomy week.—G. J. SYMONS.

### COWHART GARDEN MARKET.—DECEMBER 20.

THE usual Christmas supply of fruits and vegetables is now arriving, but with the exception of high-class goods very little business is doing, and according to present appearances this bids fair to be the dulllest Christmas we have known for many years.

From observations taken near London during forty-three years, the average day temperature of the week is 43.1°; and its night temperature 29.6°.

## A RETROSPECT OF THE CLOSING YEAR.

LOOKING forward is what all earnest members of the craft horticultural are properly doing. The old—those who have won success and honour—look for a period of retirement; the middle-aged hope for another year of still greater prosperity; and the young hope for positions of trust which they contemplate occupying worthily. Looking forward is commendable, but the path, we should remember, is hidden. All of us need a guide—the aged, the robust, the young—we all need some aid that we may pursue our way with the more confidence. Now, a guide which is at the command of all is the past. The past affords both encouragement and warning, and its teachings are recorded in the preceding issues of this Journal. We turn over its pages, and we naturally count up our loss of men whose absence we regret and whose memories we honour, yet they have left us the examples of their lives—their earnestness in the cause of horticulture, their industry, their integrity, and deserved success.

Amongst nurserymen who saw the beginning but not the end of the “closing year” the name of Van Houtte comes prominently. That “giant in horticulture,” as he was appropriately termed, lived a life of indomitable perseverance, of unflagging and almost unrelenting industry, which surmounted all obstacles. “It is not fair,” said one (who is a successful living worker) to me, “to regard that man’s life as *one* life, for a man who works unceasingly from one o’clock in the morning until eight in the evening lives the life of *two* men. Van Houtte’s thirty years of business means sixty years.” That is true, but the same lesson remains—that “he who wins must work;” and the warning is also afforded that incessant and almost unbroken labour wears out (perhaps prematurely) the strongest of men.

Another loss in the nurserymen’s ranks, and this time “nearer home,” is the blank left by the late Mr. J. R. Pearson; he also was a man of success, a man of energy, and a man of work, and one whose uprightness and conscientiousness were equal to his attainments. Mr. Pearson is remembered as having “revolutionised the character of bedding Geraniums,” as having raised new Grapes possessing both distinct and valuable qualities; but more particularly, and honourably, by having returned the highest honour which could be awarded to a seedling Grape when he subsequently found that the new Grape did not retain its youthful charms during after years of trial. The lesson left by the life of this worthy man is that high moral rectitude is more endurable than even great professional attainments. It is only the weak who (even covertly) appropriate that which is not justly their own. Mr. Pearson’s loss is mourned as one who “went straight.”

Another vacant form—not name, for that is still with us and respected, is the late Mr. W. Cutbush, who for thirty-six years laboured with assiduity in his calling:

he also was an upright man. One more name must be added to the list of the “year’s victims”—the patriarchal Mr. E. G. Henderson, who after a life of zeal resulting in the establishment of one of the foremost of the metropolitan nurseries was called away, “full of years and honours.” These are some of the men who have bequeathed to us the memory of their lives—guides of the future.

Amongst those more or less identified with the subject of botany—those who have prosecuted their researches in museums and gardens, and who have not only acquired, but have disseminated information of the greatest value, but who are “no longer with us,” may be named MM. Adolphe Brongniart and Pierre Pépin abroad, and Messrs. Bennett, Turner, and Munby at home—all painstaking workers in their several spheres, whose industry and accuracy may be emulated with advantage by others now engaged in similar important duties.

The florists’ ranks have also been thinned during the year; and how ill can real florists be spared! Nathaniel Norman, the “Tulip, Pink, and Picotee man” of Woolwich, the raiser of many of the best named flowers and the builder of his own fame by his own works, is gone. Richard Heady, whose name will be familiar for many a day, for is it not borne by one of Lightbody’s best grey-edged Auriculas? is also gone. Is not the name also attached as its raiser to that fine green-edged variety Alderman Wisbey, to the grey-edged George Lightbody, to the self Cantab, and to many others of these alpine gems; also to sundry Carnations and Picotees?—living monuments of their raiser’s fame. These men were claimed as “southerners;” but at least one “northerner” is also gone—Mr. Michael Potter of Sale, a “born florist,” and the son of the raiser of Potter’s Albion Tulip. These are melancholy blanks. Have they contributed to a “closer drawing together” of the few florists left—the union of northerners and southerners—patrons and cultivators of the flowers of earth? Surely unity is needed amongst the earnest few—an unity which it is ardently to be hoped will be signed, sealed, and ratified under the crystal dome of Sydenham in the coming year—an unity not to be disturbed by conflicting thoughts, and more especially such final separations as those above alluded to, and which all true florists mourn.

Gardeners also have been called away—Fleming, McKeith, Kinmont, Paterson, and others, who by lives of study and industry honoured the craft to which they belonged. It is only by painstaking and perseverance that gardeners can win a place in the annals of their craft; yet it is something to know that that is attainable—that is, it has been done by others besides those now mentioned, and therefore may be done again by those who will gather “lessons from the past,” and who will plod on perseveringly.

A gardener’s life is in many respects an arduous life, yet happily it is not unfrequently a pleasant life. The best of men do not work wholly with the object of laying up riches, or they would have sought out some other calling. They work for the love of the craft, and without

this devotion they cannot excel. The gardener's life is in the aggregate a healthy life—that is, it is not a killing occupation, as the average death-rate shows; but it is nevertheless enfeebling, and its votaries are subject to maladies which disable if they do not suddenly destroy. The wise will consider this and make such provision as they can. The best men of the past have exercised foresight and frugality, and the men of the present must do the same if their "closing year" is to glide smoothly away.

"Heaven helps those who help themselves" is an adage full of truth. By self help other help has been given during the closing year. Let not the examples of good afforded at least by one institution during the year be forgotten. One of the brightest pages of the Journal is in the first number for July, wherein is recorded the annual meeting of the Gardeners' Royal Benevolent Institution. There are other means than this of providing for the "unseen vicissitudes of life"—some, possibly, being more tempting; but few are more sure, more strong than the Society, rejoicing in the patronage of the Queen. I will extract a few lines from the address of the Chairman (Dr. Hogg) touching the soundness and the benefits of the Institution. "We start," said Dr. Hogg, "this year with a balance in hand of £441 9s. 8d., and our income from all sources is £1634 2s. 9d., of which £693 is from subscriptions. We have £10,750 invested in 3 per cent. consols, a balance at the bankers and in hand of £430 12s., and seventy-four aged pensioners on our list who are receiving sums of £16 and £12 a-year." Who can tell what miseries have been averted and what comforts conferred by these pensions on the persons of the venerable seventy-four? More recipients have been added to the list since then, and before the first month of the new year has passed a further enrolment of pensioners will have taken place. I have seen the list of applicants, and could not fail to note the peculiar incidence of rheumatism to gardeners who have passed through the sudden changes of extreme temperature inseparably connected with their vocation. No one knows how soon he may be smitten, but everyone may know—and I trust that not only gardeners but their employers will ponder over the fact seriously—that a guinea a-year subscribed cannot fail to alleviate the sufferings of some who have laboured in the work of horticulture, and have been the means of adding countless pleasures and substantial benefits to others in their (the gardeners') prosperity. Gardeners contributing may thus invest for their own after-benefit, and those who are never likely to want may be certain that their assistance will be well and directly applied to an object which is emphatically deserving of substantial support. The past year has taught the aged recipients how valuable is this Institution, and those who are now in prosperity will do well to commence the new year by joining this excellent organisation.

A pleasing episode of the year in connection with the Society was the recognition of services of the Chairman for his successful labours in adding to the funds for the benefit of British gardeners. All who know "the Doctor" know how earnest is his desire to improve the condition of all worthy members of the craft, and the simple address on vellum to that effect will doubtless be regarded as one of the most cherished of his many honours. Thus, if the past reveals some mournful features, it also has some pleasant points worthy of being recapitulated.

There are many other events of the closing year which may well be kept in remembrance—many records of the successful practice of present workers and of the able teachings of ancient writers. The condition of horticulture is worthy of review—the shows, the fruits, the plants, the influences of the season, the endeavours which have been made for mutual improvement, the facilities which have been provided for the growth and spread of professional knowledge by and through the gardening press. Some of these I may refer to at a future time, for I have "laid down the shovel and the hoe," and have time for reading, and perhaps I may now and again venture on wielding that potent instrument the pen. My hand may be clumsy from much hard work, but my desire is great to benefit others by the means which have benefited me.

To the Journal I can conscientiously say I am indebted for much of the success of a life of practice, and to many hours of pure and congenial enjoyment which the perusal of its pages have afforded me. Its contributors—professional and amateur—I seem to know personally, and its Editors I like to fancy are my intimate friends. If distance dispels the dream, the vision nevertheless appears to possess much natural reality, and my "closing year" is made the more pleasant. Do not

others feel much the same? I know that hundreds—thousands do, and must share my satisfaction. Let us hope, then, that we may go on as before—enjoy the same matured counsels, the same sound information, the same genial expressions, and in return give what we can, that another year—now near its dawning—may open pleasantly, progress smoothly, and close satisfactorily.

And now as my final greeting—my "last words"—of the dying year, let me wish new life to Editors, contributors, and artists.—A RETIRED GARDENER.

### SEEDLING BRIARS.

IN answer to several correspondents I wish, before giving any advice, to state that I do not believe in this stock except for Teas. My friend Hercules gave this stock a very fair trial indeed, and has, as he says, "made nothing of it at all." On the other hand a very great authority, the Rev. Reynolds Hole, states that it is the best of all stocks. So that the opinions of two of the greatest amateur cultivators of the Rose are diametrically opposed. As to where the stocks can be obtained in Devonshire, Mr. James Walters of Mount Radford Nurseries, Exeter, can supply any amount of seedling Briars. Very good they are, too, for I have seen them and talked to that good practical grower. As to continental stocks, any of the great French Rose-growers (such as Margottin, Lévêque, E. Verdier) supply them. But they are most difficult to work; and as for most soils the Manetti is a better stock, and certainly much easier to deal with, I strongly recommend it.

As to raising the Briar from seed. The seed should be gathered about November or December, and allowed to lay in a heap or pit until about the second February after—that is, about fifteen or sixteen months, in order that it may rot—that is, one summer and two winters. During this time the heap should be several times turned. After February the seed should be sown in beds and covered about an inch deep, and it will come up as thick as grass the same spring. After another year's interval the grower may bud the seedlings, and next year he will probably find ten per cent. of them have taken; and if he has patience to do all this when he can buy splendid plants for about 9d. each, he deserves to win every prize that is offered for competition the year he shows from his own seedling Briars.

There is no greater mistake, however, than to suppose that old plants will not throw good flowers. If they are properly treated they will, and it was only the other day that I heard of a grower who won the amateurs' challenge cup at Birmingham who shows from plants ten or twelve years old. May I take this opportunity of wishing you, gentlemen, and all the readers of our Journal, particularly rosarians, a very merry Christmas, though I am afraid the great day itself will be a thing of the past before these lines appear.—WYLD SAVAGE.

### MRS. PINCE'S BLACK MUSCAT.

I HAVE grown the above Grape now for the last six years, but I must confess that I have not succeeded every season in sending fruit to table in the best condition. The berries for size and flavour are all that could be desired, but I have failed in getting that finish of bloom which adds so much to the appearance, and is also one of the chief points of excellence and perfection in all black Grapes. I have one Vine growing in a mixed house, and at the warmest end, and this house is generally assisted with fire heat about the beginning of March, and the Grapes on this Vine always attain a very fair colour, which leads me to think that Mrs. Pince requires a longer season to finish-off properly than is generally allowed it, for being a late Grape it is in most cases kept back as long as possible, and only assisted with fire heat after the Vines start; and if the autumn prove dull and unfavourable, so that the Grapes are not finished-off by September, very little bloom can be put on after that.

I have likewise two late houses planted chiefly with Mrs. Pince and a few Lady Downes. The latter invariably finishes off to perfection; but it is not always so with Mrs. Pince, and notably so this season. Three parts of the berry colour very fairly, the other part next the footstalk remaining of a dull red. Now, there are some who succeed in putting a very creditable finish on Mrs. Pince, but, from what I can learn and have seen, a far greater number have failed, and amongst them some of the best Grape-growers of the present day.

Now the question arises, Are there two varieties of this

Grape (I think this has been partially alluded to before)? or, in the absence of that, is it owing to some particular mode of culture that success is attained? The first question I intend settling for myself by obtaining some eyes from Vines on which I have seen Grapes well coloured. I shall then be able to prove them side by side with my own. I shall also commence earlier this season, and see what the effect will be, as I believe Mrs. Pince, like Gros Colman, requires a long season to finish off properly. Mrs. Pince is a very superior Grape to Lady Downe's as far as flavour is concerned, but it is evident that it will not give satisfaction under the same treatment. I should be glad to hear the opinions of others, which may perhaps enable us to arrive at the proper treatment this otherwise excellent Grape requires to make it presentable at table with as much credit as we can always accomplish with its companion, Lady Downe's.—J. ANDERSON, *Hill Grove*.

## DECIDUOUS TREES AND SHRUBS.—No. 6.

**FLOWERING SHRUBS.**—The Guelder Rose (*Viburnum opulus*) is a fine old common shrub that does well in moorland near water, and is not at all particular as to soil; and the same remark applies to the Wayfaring Tree (*V. Lantana*), of which there are both dotted (punctata) and striped (marginalis) varieties. *V. macrocephalum* has splendid heads or balls of white flowers; *V. plicatum*, with its downy-leaved variety tomentosum, are very fine, also *V. dentatum*. All have white flowers in May or June. *V. plicatum* and its variety require moderate shelter. 8 to 10 feet.

Mock Orange has pretty white flowers and sweet, filling the air with fragrance, which is grateful at a little distance, but very powerful when closely inhaled. The common is best represented by its double form (*Philadelphus coronarius flore-pleno*); *P. Keteleeri flore-pleno* is equally good or better. *P. Gordoniana* with its variegated variety are fine; but the finest of the genus is *P. grandiflorus speciosus*. They flower in early June, and ought to be represented in every garden, succeeding in any soil. 8 to 10 feet.

Snowdrop Tree (*Halesia tetraptera*) is highly ornamental with its white flowers, which are freely produced in May. 6 feet.

Flowering Currants yield to no other shrubs in beauty and in the abundance of their flowers during April and May. Any soil will grow them well; all they need is an open situation. The Blood-flowered Ribes sanguineum in its varieties album, atrosanguineum, and plenum are the most desirable; but *R. aureum* is a pretty early yellow variety. *R. Gordonianum* also has yellow flowers and is very good. 6 to 8 feet.

Lilacs, common as they are, are exceedingly beautiful and succeed in any soil. In May or early June their fine heads of sweet-scented flowers are much admired. Some of the best varieties of Lilac (*Syringa*) are vulgaris, lilac; Charles X., purple; alba, white; rubra, reddish—all 8 to 10 feet. Of dwarfier growth are the Persian Lilacs (*Syringa persica*), bluish, and its varieties alba, white, and carnation (*diantheflora*), striped, with the pretty cut-leaved variety—all 4 to 6 feet. The Siberian (*S. sibirica*, syn. *rothomagensis*), purple, is later in flowering.

Kerria japonica plena has double yellow flowers in June, doing well in a sheltered situation in light soil. Its variegated form is very ornamental. 3 to 5 feet.

Honeysuckles are best represented in *Lonicera tatarica* alba, white; and in *L. tatarica rosea grandiflora*, rose, in April. 8 to 10 feet. *L. Ledebourii* flowers in summer, being yellowish red. 3 feet.

Sumach, especially the Venetian (*Rhus Cotinus*), is noteworthy, its flower-heads having a light elegant appearance, and are valuable for cutting. In autumn the whole aspect of the plant is very beautiful. *R. glabra laciniata* has its leaves so finely divided as to be very ornamental, especially from its rich tints in autumn. 6 to 8 feet.

Meadow Sweets.—Being alike free in growth and flowering these shrubs deserve to be more frequently cultivated than they are at present; their clusters of splendid flowers entitle them to a foremost rank amongst shrubs. *Spiraea arifolia* is perhaps the prettiest, having long spikes of white plume-like flowers in June and July. *S. callosa*, rose, and *S. callosa alba*, white, are dwarf and profuse-flowering, 3 feet. *S. bella*, rose, 3 feet; *S. corymbosa*, white, 3 feet; *S. Lindleyana*, white, 6 feet; *S. Douglasii*, pink; *S. Nobleana*, pink, 3 feet; and *S. ulmifolia*, white, very good, 3 to 5 feet; all flowering between June and August. *S. prunifolia flore-pleno* has yellow flowers in early summer, 4 to 5 feet; and *S. Reevesii flore-pleno*, yellow,

low, flowers in April and May, 3 feet. *S. Thunbergii* is of graceful habit, having white flowers in June, 3 feet. *Spiræas* like a free, open, and tolerably moist soil.

Weigelas flower in April to June, and are very beautiful and sweet. They like a free open soil, and do well in peat. *W. amabilis*, rose, and its vars. *alba*, *Grænewegeni*, *Van Houttei*, both pink or rose, with *Stelzneri*, red, are the best varieties, but are not so neat in habit as *W. rosea*, which flowers later. *W. hortensis nivea* has fine white flowers, and the variety of *rosea*, *Madame Couturier*, white, is very fine. All 4 to 6 feet. *W. rosea nana variegata* is beautifully variegated and dwarf, 2 to 3 feet; *W. arborescens versicolor* is desirable for its striped flowers, and *W. multiflora* for its free-flowering, deep scarlet.

*Forsythia Fortunei* and *F. viridissima* afford yellow jasmine-like flowers in spring before the leaves, and are very desirable. 6 feet.

*Deutzia gracilis* is very beautiful in April from its white blossoms, and is well known as a fine forcing plant. In an exposed situation outdoors it does not succeed, and prefers free open soil; 2 to 3 feet. *D. crenata flore-pleno* is very pretty from its double pink flowers profusely produced in June. It grows very freely, even in an exposed situation; 4 to 6 feet. The double white, *D. candidissima flore-pleno*, flowers abundantly; 4 to 6 feet. *D. scabra* grows even more freely, and may be mentioned as suitable for moist soils.

*Cydonia japonica*, red, and its varieties *candidissima*, white; *lutea viridis*, yellow; *alba*, pinkish; and *plena*, double red, produces their flowers from February to May, most profusely in April, their high-coloured large flowers having a fine appearance. They like a free open soil. 4 to 6 feet.

*Daphne Mezereum*, pink, and its red and white varieties, with *D. Fortunei*, lilac, are very desirable from their early flowering (February to April) and fragrance; 4 to 6 feet. They bloom very freely in a young state.

*Hydrangea hortensis* and *H. japonica* vars., unfortunately, are not hardy, except in warm sheltered situations; but where they do succeed no other shrubs have such magnificent heads of flowers. In exposed situations the plants are herbaceous. They are not recommended only for warm situations, but *H. paniculata grandiflora* has a very ligneous growth, and is very much more hardy. Its flowers, or rather bracts, are produced in very large heads, creamy white in colour, blooming in late summer and autumn, having a fine effect. *H. Otaksa* has very large rosy heads of bloom, very fine. *Hydrangeas* generally are more intense in colour when grown outdoors, and plants after flowering indoors will, if placed outdoors, have the bracts changed to a bright red. 3 feet.

*Althæa frutex* or *Hibiscus syriacus* is very free late summer and autumn-flowering shrub, which requires a sandy soil and an open yet warm sheltered situation. Good varieties are *azurea plena*, *elegantissima*, *Leopoldii*, *purpurea flore-pleno*, *Duc de Brabant*, *Duchesse de Brabant*, *Lady Stanley*, *ardens*, *speciosa plena*, *carnea tricolor*, and *ranunculiflora plena*. 6 to 8 feet. In cold situations they do not succeed, otherwise they are very desirable from their late blooming.

Barberry (*Berberis vulgaris*) will grow in almost any soil, and is very hardy; the flowers are yellow, very pretty in spring, and the fruit is not less so in late summer. The variety *alba* has white fruit, *lutea* yellow fruit, and *purpurea* has purple leaves. 6 to 8 feet.

*Calycanthus macrophyllus*, or the American Allspice, has chocolate-coloured flowers, and sweet throughout the greater part of the summer. 6 to 8 feet.

Bladder Sennas are handsome shrubs which need a free open soil and shelter from winds. *Colutea arborescens* with yellow flowers, and *C. cruenta*, scarlet, are most desirable. 8 feet.

*Clethra alnifolia* is a very pretty dwarf shrub, having clusters of white flowers in August. 3 to 4 feet. It prefers peat soil.

Scorpion Senna (*Coronilla Emerus*) is attractive from its yellow flowers in May, and is also elegant in habit. 4 to 6 feet.

*Edgworthia chrysantha*, a low-growing shrub with golden balls at the end of the shoots in June, is worthy of mention. It is of doubtful hardiness in any but sheltered situations and well-drained soils. 3 to 4 feet.

Fuchsias in all but sheltered situations and dry soils are herbaceous, nevertheless they ought to be in every garden. *F. pumila*, *F. Riccartoni*, and *F. virgata* are good.

St. John's-wort is very useful in dry soils or banks. *Hypericum oblongifolium* has fine yellow flowers in late summer. *H. floribundum* and *H. hircinum* are also good. 3 feet.

*Indigofera floribunda* has fine pea-shaped flowers in late summer, and *I. decora alba* affords a good contrast. They like a free open soil and shelter, but moisture when growing. 2 to 3 feet.

*Jasminum fruticans* with *J. nudiflorum* have yellow flowers, the former in summer and the latter in midwinter. In sandy soil they, though classed as climbers, form spreading shrubs.

*Leycesteria formosa* has white and purple flowers in August, and its fruit is very greedily eaten by pheasants. 4 feet. It likes free open soil.

Tree Paeony deserves to be more frequently seen, and in greater number. Few plants have such large, varied, highly-coloured noble flowers. They prefer free open soil and sheltered situations. There are many fine continental vars. 3 to 6 feet.

*Prunus triloba* has fine pink flowers profusely produced in April. 6 feet.

Cinquefoil (*Potentilla fruticosa*) affords yellow flowers in summer, and has silvery foliage. *P. floribunda* is more free-flowering. 3 feet.

Brambles are so common that no one cares to have them, and yet the Sweet Bramble (*Rubus odoratus*) has showy pink flowers in July, and many others are worthy a place, especially the variegated Bramble; and Sweet Briar fills the air with fragrance, and is very effective from the profusion of its hews and their orange colour. It should be planted by thousands.

The preceding strike me as some of the most desirable of deciduous shrubs which I have seen and have taken note of; and now that there is an apparent desire for subjects of interest and variety, and as the claims of deciduous shrubs are great, it is hoped those who can see beauty and interest in something taller than an herbaceous plant will perceive that many shrubs of late neglected await their acceptance in deciduous as well as in evergreens.

*Azalea pontica* vars. appear in fine contrast with *Rhododendrons*. The light green of their leaves stand out grandly in contrast with the dark foliage of *Rhododendrons*, and their flowers are equally effectively contrasting, and have a delicious fragrance. The Ghent varieties are the largest flowered, and are mostly high coloured, as orange, scarlet, flame, &c., descended from *A. calendulaceum*. The light-coloured or white varieties are offshoots of *A. viscosa*, in which are found the smallest flowers with the highest fragrance; and the pinks, roses, and purples are larger in flower than the last, but smaller than the first, having a very twiggy growth. The plants thrive in any good loamy soil on a cool bottom, peat being no more absolutely required for their growth than *Rhododendrons*, and hares and rabbits have as great a repugnance of *Azaleas* as of *Rhododendrons*.—G. ABBEY.

#### SPECIAL SOCIETIES FOR THE ENCOURAGEMENT OF FLORIST FLOWERS, &c.

ONE of your contemporaries publishes an article in a recent number on what it calls "Special Societies." The article in question is probably meant to be amusing, but its tone is rather dolorous nevertheless. It looks upon such societies as "a most unwelcome symptom of decay and disintegration of what ought to be the central body." Your contemporary does not hope to check "the tide;" he would evidently do so if he could—that is, unless they could all be banded together for "the common good." The promoters of such societies are also kindly told that "every man has a right to choose his own recreation, and to indulge it so long as he does not hinder his neighbour in the prosecution of the same wholesome object; only don't let him fancy he is promoting some great and worthy object, such as horticulture for instance." Your contemporary surely cannot be ignorant of the fact that such "special societies" have been in existence for more than half a century, that they were in a prosperous condition before its first number was printed, and that they continued to prosper simultaneously with the great central society, which is evidently alluded to.

My object in writing to you at this time, however, is not to find fault with the remarks made in another paper, but to put in a plea for one or two of the so-called "special societies." First in order is the National Auricula Show, to be held at the Crystal Palace, Sydenham, in April next, and this will be upon a scale commensurate with the estimation in which the Auricula is held. In 1864 the National Auricula Show was held in the Royal Botanic Gardens, Regent's Park, on April 30th. Since that time the Auricula has been much more extensively

cultivated, and for one plant exhibited in 1864 we expect ten in 1877 at the Crystal Palace. One great grower who held a high position in that year will be missed—Mr. Heady of Stapleford, but we shall have others who have since risen to a very high position in the culture of this flower. I do not find the names of Horner, Simonite, Barlow, Royds, Gorton, and others, now well known in the north, as exhibitors thirteen years ago, but whom we hope to meet next season. Another very cogent reason for holding an Auricula show next year is this, that very probably the Royal Aquarium Company and also the Royal Horticultural Society will not be in a position to do so.

A Carnation and Picotee show has also been in contemplation, to be held in the south. Some of the best growers of these flowers have been removed by death or other causes, but it can easily be seen by referring to the prize list of last July at South Kensington that others equally good have taken their places, the exhibitors having been much more numerous than they have been for many years, and the flowers were of the best quality. Now, if no Society is in a position to offer prizes for them at the right time, which is the 20th of July for London, and if the growers of them band together and raise money for a prize fund amongst those interested in their culture, are they to be told for the first time during the last fifty years that they "must not suppose they are promoting some great and worthy object, such as horticulture for instance?" Does it not seem very much like an insult to honest industry to throw such a remark in the face of such a man as Mr. Benjamin Simonite of Sheffield for instance, who has worked with such patient industry for nearly forty years in raising such flowers as he has done, and bringing them before the public through the medium of the National Carnation and Picotee Society? It is encouraging to such men to feel that others appreciate their labours, as in addition to Manchester the National will probably hold a show at Leeds next season. If, as is very probable, a show can be held in London, there will be no lack of exhibitors, and no Society, large or small, will suffer, and let us hope the cause of horticulture will be no loser.

Then we come to the Tulip, and it does seem passing strange that such a glorious flower is not more grown. What other flower bed can compare with a bed of Tulips in May? To grow Tulips to perfection it is necessary to go to some expense in the way of preparation of the ground and erecting some protecting material to shelter them from the heavy rains which lodge in the axils of the leaves, and from frosts which freeze the gathered water and injure the blooms; but let not the patient and laborious florist suppose that if he ventures to place his perfect flowers on an exhibition table he is "promoting the cause of horticulture for instance," if he ventures to give his money and, what is often to him of much higher consideration, his precious time in sustaining a society for its encouragement. But let me ask, Why are there so many ardent cultivators of the Tulip in the neighbourhood of Manchester and so few near London? There is, and let us utter the word cautiously, a "National" Tulip Society there. It is moveable, as all societies worthy of the name ought to be. It was held at Manchester last year, it is prosperous, and new growers are yearly added to its ranks. The general public see the flowers, they go home and think about them, they wish to grow a collection, and many become growers who will not exhibit; others are advanced to the grade of fanciers, and they wish to place their flowers beside the noted growers, and none but a true florist knows the hours of happiness experienced in watching the development of this or that flower, obtained with difficulty, and tended through winter snow and summer heat with loving and unceasing care. Does any Society consequently suffer? Is the cause of horticulture promoted, or is it not?

Roses—they ought to have come first, for the Rose has many advocates; but one question only—Did the National Rose Show injure the Royal Horticultural Society, or has the National suffered by its contact with it? Let the Rose-growers answer. But what about a National Onion Show? O ye men of Banbury! will you dare to table your White Spanish before you are "thoroughly well versed in general horticulture?" Ye artisans of Sheffield! how can you pour the liquid manure to the roots of your mammoth red Cabbages? How can you mulch them round the roots and wheel them to your annual exhibition, each one large enough to fill a barrow, and you not "thoroughly well versed in general horticulture?"

Well, then, the question that arises is this, How is horticulture best promoted: by large shows or small shows? I say, By both. Take any district (and I have had experience with many);

when a flower show has been established, year after year the exhibitors become more proficient, and the productions they exhibit and which they place before their employers (if gardeners) are improved year after year. And the societies that have been formed for the encouragement of florists' flowers cause the florists themselves to take a greater interest in them, to grow their flowers better; and the general public, who have no other opportunity of admiring them, can do so at the exhibitions, and a love for the flowers is fostered and spreads into places where they were before unknown. This many florists can abundantly testify. Let us encourage them all we can, from the lovely queen of flowers even to the humble Cabbage, and when the Royal Horticultural Society has been released from the fetters with which it is still bound, those at the head of affairs will find the work has not been neglected. We shall be pleased to hand it over to them, and the work will go on prospering and to prosper. The work of Mr. Wilson will not be in vain. Thousands of Fellows will rally around the old Society, and its last days will be its best days.—J. DOUGLAS.

### BUTOMUS UMBELLATUS.

To say that this flowering Rush is a lovely flower is saying a good deal, but that falls far short of what might be said of one of the finest hardy aquatic plants that we possess. It

Fig. 79.—*Butomus umbellatus*.

is mostly met with by the sides of sluggish streams and partially stagnant ditches and watercourses, and must be seen in its native home to be seen in all its beauty. It is said that the sharp edges of the leaves of our favourite plant cause the mouths of oxen to bleed when browsing upon it. We may reasonably suppose from the above that its rough edges are intended for a protection. Gerarde says, "The water Gladiolus, or Grassie Rush, is of all others the fairest and most pleasant to behold, and serveth very well for the decking and trimming-up of houses because of the beautie thereof." The finest plant in cultivation I ever saw was in a pond in the garden of Dr. Herbert at Spofforth many years ago. It was placed on a pedestal in the centre of the pond in a large pot about a foot below the surface of the water. When in bloom it was worth

a day's journey to go and see. Native though it be, it requires care to get it established. I find it a good plan to establish the plants in pots, then sink the pots in a muddy bottom, when the plants will take care of themselves. They may be potted in any good loam, and are increased by division when growth is commencing. They are telling plants in a collection of native plants on an exhibition table.—N.

### TRAINING VINES.

LET me thank Mr. W. Taylor for his account of training Muscats on the extension system. Practical men like to see depicted the works and the places which are worthy. An illustration which appeared in your pages some months ago showing a splendid crop of Grapes grown by Mr. Cottingham of Heath near Mansfield was a worthy example for other growers to imitate, and could not have been sufficiently represented without the artist's aid. The figure of Mr. Taylor's vinery shows no such crowding of bunches, but it shows a disposition of wood which has assisted the Vines to become extremely vigorous, which have carried splendid Grapes, and will yet produce more.

The mode of training illustrated is both suggestive and instructive. It not only shows what Mr. Taylor told us in his notes of the horizontal main rod being trained past the "nursing" Vines, but it shows what he did not tell us of the remarkable strength of the Vines from the ground to the bottom of the rafters and the diminishing strength of the canes as they reach the top of the house. This is just as it should be, but how seldom is it accomplished! Many more than half of the Vines in Britain are the smallest nearest the ground, and consequently the thickest at the top. When in that condition it follows as a matter of course that the first flow of sap has to traverse restricted channels. In the case of Mr. Taylor's Vines the first outflow is unimpeded, for the first few feet of the stem is of marvellous thickness in comparison with the upper growth. How has this been effected? I think the illustration shows it.

In the first place Mr. Taylor appears to have encouraged the growth of some foliage even down to the ground. That is undoubtedly most important in influencing the correct thickening of the stems of the Vines. How often do we see the growths rubbed quite off the stems from the ground to the rafters—perhaps even before the Vines are planted, or at any rate immediately afterwards! That is a common practice, but a great mistake. If the lower portion of the stem of the Vine is denuded of its buds in infancy and made as smooth as a water pipe it will not swell much faster than will that pipe; but allow the leaves to remain, and the stem will increase in size in a natural manner, and certainly to a beneficial end. Mr. Taylor knew better than to denude the lower portion of his Vines of foliage; he left a portion to attract and retain the sap where it was especially required, and thus laid the foundation of his robust Vines. Those who are planting Vines will do well to follow the example thus given.

Another important matter is in equalising the flow of sap by the mode of training which has been adopted. The flow of sap has something in common with the dispersion of smoke. With a straight upright shaft direct from the fire the smoke rushes upwards with great force, and will turn a "jack" which the strength of a man cannot resist; but first conduct the smoke along a horizontal flue before it is permitted to ascend vertically, and a child may prevent the "jack" from turning if it is placed beyond that horizontal flue. The strength of the smoke, so to speak, is exhausted at the base of the building by the counteracting influences of the horizontal flue preventing its violent rush upwards. It is the same with the sap of the Vine, but to a greater extent in consequence of its greater velocity and force. I have read that an old author and experimentalist, who made elaborate experiments on the force of the sap-movement of the Vine, found that in a mercurial gauge fixed to the bottom of the Vine the mercury was raised by the force of the sap 38 inches, equivalent to a column of upwards of 43 feet of water. I think that fact (for I am not aware that it has ever been disputed) is well worthy of consideration in reference to training Vines.

A horizontal flow checks the violent upward rush of sap, which is the real cause of so many Vines being too weak at the bottom and over-luxuriant at the top. If all the growths were trained horizontally the Vines would probably be deficient in vigour; but by the practice adopted by Mr. Taylor of taking vertical or nearly vertical rods from the horizontal

main, a free, regular, and healthy sap-movement is fostered and the Vines thicken at their lower parts and produce there laterals and bunches equally as fine as at the tops of the canes. I am well aware that Vines will thus bear without a horizontal main rod when judicious pruning is adopted and the lower laterals have that attention which is given by the best cultivators; but I am nevertheless of opinion that Mr. Taylor's plan is the best in principle, and is calculated, with a minimum amount of care being bestowed, to produce a maximum value of fruit, and especially an equal distribution of that fruit on every part of the Vine.

But without adopting the extension system of growing the Vine much may be done by training in securing an equalisation of fruit, and in having the lower portions of the stems of Vines as thick or thicker than the upper. If Vines on the single-rod system are trained slantingly at an angle of 45° instead of tying the rods directly upwards, the growth is more regular, in consequence of the sap being more surely guided into the lower laterals, yet it has sufficient force for ensuring growth sufficiently robust. I fancy I can perceive in the illustration that Mr. Taylor's fruiting rods are trained slantingly notwithstanding the horizontal main, and no doubt he is quite right in so training them, for it is the very position which the young growths would seek for themselves, thus giving a hint which an observant and practical man would be likely to follow.

Vines grown on the restricted or single-rod system I have found to be decidedly superior when trained slantingly than when what I may term vertically trained. This has been so in a house having a great length of rafter, and the advantages can hardly fail to be still greater in short-roofed vineries, for it is clear that by training slantingly a much greater length of cane is obtained, and which is often of great value in contributing to the Vine's health and its continued prosperity.

In this mode of training one condition must be carefully attended to—the rods must not be too close together. I know it answers well when the canes are trained 3 feet 6 inches apart. I should not think it wise to adopt the system with rods much closer, or the foliage might not receive sufficient light, and especially if the roof of the vinery was somewhat flat.

I think the training of Vines is important as exerting considerable influence on growth. The matter is worthy of being alluded to by other growers who have studied the habits and requirements of the Vine. If gardeners are "the slaves of fashion" in one thing more than another, I think it is in limiting Vines, however short they may be, to one rod, and training that rod over the shortest course to the apex of the house in a manner as nearly vertical as the circumstances will permit.—A NORTHERN GARDENER.

#### A PLEA FOR JAPANESE CHRYSANTHEMUMS.

"WHAT lovely artificial flowers! What beautiful paper flowers you have there!" These were the exclamations accorded by some visitors a few days since on seeing a stand filled with cut blooms.

They were indeed wrong in their judgment, but many of the Japanese Chrysanthemums may be likened unto artificial flowers from their grotesque appearance. The fantastic and twisted florets of some bear a very close resemblance to artificial flowers. The Japanese possess many advantages over the round incurved varieties, having a lightness of their own. They are among the first to bloom, James Salter and Elaine being the earliest; the first a pleasing lilac, the other pure white, and a well formed flower under high cultivation; and in this section are also to be found some of the latest to bloom of the whole family, and which will assist in keeping the conservatory gay to the end of the year.

I have now before me (December 23rd) creditable blooms of Meg Merrilees, The Mikado, and Grandiflora, but the majority are over; still with a selection blooms may be had from October to Christmas, and in arranging them for home decoration they are most suitable, keeping for weeks in dry rooms if the water is attended to.

Their culture is very similar to that already advocated in previous articles, merely taking strong cuttings from now till March, and growing the plants on without interruption, dis-budding for early flowering and exhibition purposes; but if late blooms are desired dis-budding need not be resorted to, but the smaller and later buds should be permitted to expand. I have never seen these plants grown into specimens, still I

think it possible that James Salter, Magnum Bonum, Fair Maid of Guernsey, and some others might be advantageously used for that purpose. Some of the varieties are very shy in throwing-up suckers for propagation, and others increase most readily.

The following will be found a good selection of eighteen varieties:—James Salter, Elaine, Fair Maid of Guernsey, Fulton, Baronne de Prailly, Magnum Bonum, The Mikado, The Daimio, Chang, Auratum, Meg Merrilees, Madame Godillot, Erecta Superba, Prince Satsuma, The Wizard, Garnet, Dr. Masters, and Grandiflora.—J. W. MOORMAN.

#### CUCUMBER CULTURE.

I QUITE agree with your correspondent (page 516) as to turfy loam and manure water instead of mixing manure in the soil, as I have grown Cucumbers both ways, and in 1874-5 I grew rather largely for Covent Garden Market.

The Cucumber houses were four span-roofs—two 96, and the other two were 100 feet in length; of course it was no use putting a few seeds in a bell-glass or a single flower pot, so I put the seeds in some shallow boxes and placed them in the propagating pit, and as soon as the plants were large enough to handle I potted them into 60-sized pots, from them into 48-sized pots, afterwards planting in the beds in turfy loam. For the first month they received clear water only, and then I commenced using weak manure water twice a-week, and continued doing so throughout the season. As soon as the roots were well through the soil a thin layer of fresh loam was added all throughout the season, and the result was I lost only one plant the first year and none the second, and no plants could have been healthier nor could have fruited better than they did. I feel sure that if the manure—which very often contains a quantity of grubs, &c.—were less used Cucumbers would be more plentiful. I am still of opinion that manure has something to do with the plants being so liable at times to disease.

As to sorts, I have tried a large number from time to time which I have seen recommended; but with me, either for market or for private use, I have never found any to beat Telegraph, Sion House Improved, and Munro's Rabley, which I have proved to be quite as hardy or hardier than Telegraph.—J. B. WETHERINGSETT, *Stonham, Suffolk*.

#### THE CHRISTMAS MARKET AT COVENT GARDEN.

SATURDAY morning, the 23rd inst., was a "lively time" at Covent Garden, when the best of garden supplies were struggled for even with unusual zest (if that is possible here), for the vast requirements of London during the festive week. There is no mistake about the citizens enjoying themselves at Christmas. The festival is prepared and provided for months previously, and the humblest are not satisfied with less than the "best" of what is provided at this special season: hence the piles of vegetables were hurried off almost before daylight. The residue remaining at nine o'clock was composed mainly of the coarser vegetables, such as Savoys, Turnips, &c. Broccoli (Snow's Winter White) was speedily seized, also the best of the Brussels Sprouts, and there was the usual rush for Sage and Onions. The vegetables were generally good, thanks to the long mild autumn, except Potatoes, and these were coarse. Seakale and Rhubarb were plentiful and good. Asparagus was also represented but sparsely, and salads of all kinds were abundant. Holly was unusually destitute of berries, and Mistletoe, perhaps, unusually fruitful.

The flowers were very attractive, and "shined through the gloom" of the foggy sleety morning. Poinsettias were brilliant with their fiery heads, and baskets of Roman Hyacinths were lovely in their snowy whiteness. Dutch Hyacinths were also "in" in their various colours, and were excellent considering their earliness. Duc Van Thol Tulips—white and scarlet—as mixed in close large masses had a most cheerful effect. There were also Heaths, Azaleas, Callas, Solanums, Dracenas, Palms, Primulas, and Lily of the Valley.

But as if these were not enough, or their price, perhaps, too much for many, there were artificial plants and flowers struggling through the mist, as if trying to look natural, and almost succeeding. There were "vegetable flowers," too—flowers delicately carved from roots and tinted with various colours. The designs formed with Everlasting Flowers were numerous and tasteful, white largely predominating in their

arrangement, the touches of the warmer colours being extremely slight. Camellias, Roses, Bouvardias, Azaleas, and Lilies were the prevailing flowers for bouquets and "button-holes."

Fruit was not as a whole superior. The best Grapes were Lady Downe's in the window of Messrs. Webber; there were also fairly good Muscats. The general bulk of the Grapes on sale was, however, inferior. Pines were of average quality, in perhaps under-average numbers. Pears and Apples were moderately good—Lady Apples from America being extremely high-coloured, and shone as bright as if "iled." It was not an aristocratic market, but the produce was such as to suit the average Londoners at their annual feast.

## ROYAL HORTICULTURAL SOCIETY.

The following address has been issued by the Council to the Fellows of the Royal Horticultural Society:—

Before the commencement of a new year the Council are desirous to make the Fellows of the Society acquainted with the actual position of their affairs.

On the 2nd August last, at a public meeting of the Fellows, the following resolution was carried:—

"This meeting approves of the policy of the Council in endeavouring to effect a separation of interests between Her Majesty's Commissioners and the Royal Horticultural Society upon equitable terms with the Debenture-holders and Life Fellows, and requests the Council to urge an early settlement with Her Majesty's Commissioners."

The Council being advised that this separation could only take place with the concurrence of the Debenture-holders, placed themselves in communication with a duly appointed Committee of that body, and with Her Majesty's Commissioners.

On the 27th October the Council received from the Secretary to the Commissioners a copy of a resolution passed at their last meeting:—

"That the Special Committee of Inquiry should be authorised to conclude an arrangement with the Royal Horticultural Society for a termination of the lease of the Horticultural Gardens on the footing of a payment to the Society for the Debenture-holders of the present value, calculated at 84 per cent. of the sum which may become payable by the Commissioners to the Society in 1892—namely, half the debenture debt, with power for the Special Inquiry Committee to make an arrangement as to the goods of the Society should they see fit."

This resolution was forwarded to the Committee of Debenture-holders on the 2nd November.

A meeting of the Debenture-holders was held on the 23rd, and the following resolution was passed:—

"That this meeting declines to authorise the surrender of the lease of the Gardens to the Commissioners on the terms mentioned in the letter of the Society of the 2nd November, 1876, and the meeting will not authorise a surrender of the lease unless provision be made for the payment of the debenture debt in full, by reasonable instalments with the interest in the meantime, and that a copy of this resolution be forwarded to the Society."

In these circumstances no course appears open to the Council but to continue their tenancy of the South Kensington Gardens.

In the absence of subscriptions sufficient to maintain these Gardens in proper repair, they would gladly have surrendered them had they been in a position to do so, and have devoted themselves to the promotion of the objects of the Society in its strictly scientific character.

But this separation being for the present impracticable, it will be the duty of the Council to apply such funds as they may receive in accordance with their Charter.

The Scientific, Fruit, and Floral Committees will conduct their operations as hitherto, scientific experiments will be continued at Chiswick, the fortnightly meetings at South Kensington will be held as before, one great show at least will be held in London, and arrangements will be made for holding annual provincial shows in some populous centre.

The maintenance of the Gardens at South Kensington in their previous condition must depend upon the desire of the inhabitants of that neighbourhood, as expressed by their subscriptions.

The Council have already announced that these subscriptions not only fall far short of the sum (£10,000), on the collection of which at the end of three years from December, 1875, the continuance of their lease of the South Kensington Gardens will depend, but are at present insufficient to maintain those Gardens in a befitting state.

Should the annual subscriptions continue inadequate for this purpose during the next two years, the Council can only look forward to the termination of their lease by the action of the Commissioners.

In the meantime the Council will spare no effort to prevent this unfortunate termination of a scheme launched under such high hopes and promising auspices.

The Council having reason to believe that the table of payments and privileges in force in and before 1872 is generally considered as more acceptable than that now in force, have

determined to revert to it, with this additional concession, that the two-guinea Fellows will have the privilege of one transferable ticket;\* and in order to facilitate an increase of members, the rule as to the payment of entrance fees will be suspended during the year 1877.

It is also proposed, subject to the sanction of a general meeting, to admit members of the Society upon the payment of one guinea annually; such members to have all personal privileges of Fellows except that of voting at the meetings of the Society.

For the convenience of the Fellows the new table of payments and privileges is appended.

### SUMMARY OF THE PRIVILEGES OF FELLOWS FOR THE YEAR 1877.

#### *Privileges of a Fellow paying Four Guineas a-year.*

1. Entitled to two yearly tickets, both of which are transferable, and which give the bearer personal admission every day, and to all Shows, Fêtes, Conversazioni, and Promenades, both at Chiswick and South Kensington. (When the Fellow exercises his or her privilege of entering the Gardens, one of these tickets must be used by him or her.) N.B.—The Garden at Chiswick is closed on Sunday, and the Garden at South Kensington is open from 2 P.M.
2. The right of introducing two friends with the bearer of each ticket on every day of the week. (Show and special days excepted.)
3. The power of admitting daily (Sundays excepted) eight friends by written order to the Garden at Chiswick.
4. To visit the shows at an earlier hour than the general public.
5. To purchase for £2 2s. each, transferable tickets, which confer on their bearers all the privileges of personal admission and of introducing friends that the Fellows themselves could exercise.
6. To receive forty orders giving free admission to promenades and on all days excepting show days and special days.
7. The right of purchasing, previous to the day of the shows or promenades, tickets at reduced prices.
8. A share of such seeds, plants, and cuttings of Vines and fruit trees as the Society may have in sufficient numbers for distribution by ballot or otherwise.
9. To purchase the flowers, fruit, &c., grown at Chiswick which may not be required for the use of the Committees.
10. To receive a copy of the publications of the Society.
11. The right of voting at all meetings.
12. The right (on giving notice in writing) of being relieved from the yearly payments while resident abroad.
13. Free admission to the reading room and Lindley library.
14. The wives or husbands of deceased Fellows, upon being themselves elected Fellows, are exempted from the admission fee.

#### *Privileges of a Fellow paying Two Guineas a-year.*

15. Entitled to one yearly ticket, transferable, admitting the bearer every day, and to all Shows, Fêtes, Conversazioni, and Promenades, both at Chiswick and South Kensington, and the bearer with two friends on all ordinary days.
  16. Entitled to half the privileges mentioned in Nos. 3, 6, and 8.
  17. The same as Nos. 4, 5, 7, 9, 10, 11, 12, 13, and 14.
- The Society has no debts; its Debentures are a charge on its surplus income only, and being incorporated by Royal Charter, the Fellows incur no personal liability beyond the payments of their annual subscriptions.

## GARDENING REMINISCENCES OF THE PAST FIFTY YEARS.

THE end of one year and the beginning of another would seem a becoming time to take a retrospect of the past; I will, therefore, avail myself of the license usually granted to those of mature years, and will endeavour to call to memory something of matters relating to the calling at a time when gardening periodicals were unknown and the number of standard works bearing on the craft were also limited, but which, I may add, were mostly highly respected by many admirers. Our north-country brethren had their Nicoll and subsequently a McPhail, while those of the south had their Abercrombie and Forsyth; and the "Botanical Dictionary" of Miller was one of the standard works often referred to as unique in its way, while some works of lesser account represented all that was thought prudent to publish on the culture of flowers. It is right here to say that the age was one of exclusiveness, as there was assumed a sort of secrecy in the art of cultivating certain plants which it was thought improper to make too generally known. Modes of growing Auriculas, Pinks, Tulips, Ranunculuses, &c., were pretended to be kept as profound

\* The recent agreement with the Commissioners will, however, prevent the fresh creation of any life privileges.

secrets by those entrusted with them. But the age of enlightenment began to dawn on such matters, and the appearance of that great pioneer of gardening periodicals London's "Gardeners' Magazine" led to the divulging of many of the so-called secrets which were supposed to be necessary to ensure the good cultivation of certain plants. But even this was very tardily accomplished, and I well remember a successful grower of Tulips offering through the pages of the "Magazine" to divulge to twenty subscribers that would pay him a guinea each his mode of inducing the finer varieties of Tulips to break out into offset bulbs with greater facility than they were wont to do. This offer, as might be expected, led to many conjectures, which appearing in print, no doubt some of them giving the hint to the mode practised by the supposed successful cultivators, added to which the known antipathy of the talented conductor of the journal to everything that tended to concealment of anything useful to mankind, aided by the greater diffusion of knowledge that was then springing up, tended, as is usual, to the other extreme—excess, and it became customary to scoff at everything that was made known. But certainly the public at large were gainers by the matter, although it took some years to effect the object.

I well remember the time when it was customary for a visitor to a nursery at grafting-time to find when he approached the man performing the operation that the knives all wanted sharpening, and that scissors were not at hand, but had to be sent for, and did not arrive till the stranger had gone. Other things were done in the same exclusive manner, and it was only by degrees that a change could be accomplished, yet the change did take place, and the cheapening of literature which followed towards the close of the third decade of the present century assisted materially to bring about a more liberal state of things.

But it must not for one moment be supposed that I here disparage all that was done by the class of cultivators at that early period, and I question much if the culture and management of Auriculas, Pinks, Tulips, Ranunculuses, and some other flowers are as well understood now as they were then, and the number of varieties of each were as numerous then as now, and I am not sure but that some of the kinds known then are still held to be good now. I have sometimes been agreeably surprised in this neighbourhood, where fruit is largely grown, to find that some of the Lancashire Gooseberries that I was frequently brought in contact with years before the passing of the first Reform Bill, are the favourites here grown for market; notably one which a friend told me not many weeks ago, called Lancashire Lad, is wanted at the present time—the autumn of 1876—by tens of thousands, while Crown Bob, Ploughboy, Roaring Lion, and others have all had their day and have been more or less admired. We must not be too hasty at charging our predecessors with any lack of the knowledge necessary to good cultivation; and as these Gooseberries were grown during the reign of the latter Georges, we must give those growers the credit that is their due. I well remember the time in which prizes obtained for large Gooseberries were exhibited by their respective winners with great pride. Many other things were also patronised at the same time, and I am far from certain but that better Melons and Cucumbers were grown then than now, although the accommodation for that purpose has been widely increased since.

It would not be fair to pass over the period above alluded to without noticing the habits of the young men who followed the calling of gardeners at that time. Well, then, I may say that as a whole they paid more attention to botany than is generally done by the same class now-a-days, and the immediate district in which they lived was duly scoured for rare specimens of British plants, besides now and then long journeys taken to some locality more rich in what was considered valuable and scarce. I well remember a place where that difficult plant to propagate, *Cypripedium Calceolus*, was said to be found, while other localities yielded the Butterwort, Pennywort, and other favourites. Ferns were not so much studied then as since, but botany as a science was pursued with more zest at that time under the Linnæan system than it has been since that system has been to a certain degree superseded by the natural system. But the young gardener's attention was not monopolised wholly by wild plants. New and promising species of plants were added to the class of what we may call florist flowers. The Dahlia, which had made its appearance a few years before, was fast merging from the single to the double condition, and new names had to be coined for the new varieties resembling in many respects those in existence for Auriculas,

Polyanthuses, and the like. The Pansy too followed suit, while the greenhouse and plant stove consisted more of botanical collections than the same structures do now. But a change was coming, and the large and fine collection of Cape Heaths which had taken years to collect were giving way to garden varieties of the popular Pelargoniums; and the old Scarlet, which was often met with growing against the back wall of some glass structure, was also on the point of being improved upon. And I well remember the noise that was made when a "White Scarlet" made its appearance, while amongst the earliest improvements on the old Horseshoe was Brighton Hero, Sol, and a strong-growing one the name of which I cannot now call to memory.

Amongst the fruits which received especial attention at this time the Peach may be mentioned, and if we could see placed on the exhibition table at the present day a dish of the fruit produced at that time it would compare very favourably with modern productions; while the trees which produced the fruit, their appearance and the mode in which they were managed, would be equally favourable to the certificate for good culture being awarded to the earlier cultivators. Other fruits were not neglected. The varieties of Strawberries were far from numerous then; but one kind at least made its appearance then or soon after, which still holds a good position at the present day, and it is questionable even now whether any variety is cultivated to as great an extent in 1876 as Keens' Seedling, which first made its *début* some fifty years ago. I fear I cannot say so much in favour of one that succeeded it with a high-sounding name, and coming at the same time from one of the most successful growers of this fruit at the time speedily fell into disrepute. Wilmot's Superb shared the fate of many a one since, and it is now, I expect, numbered with the past. But the great favourite was the Gooseberry, for which there were village shows at most places where as many as twenty dwellings were congregated together, size and weight being the object aimed at. An application of the same principle found expression in another form, and the Giant Rhubarb owes its origin to that period, whilst very large Celery was also produced. I think among other useful vegetables the Brussels Sprouts was not much known until this time, when its usefulness was duly acknowledged, but I do not think it was until some years afterwards that any especial improvement took place in Peas.

For some years after the period above alluded to nothing particular occurred in the usual routine of the gardening world but that slow but steady increase of knowledge consequent on the cheapening of literature which took place then, and the commencement of new and popular works of instruction and entertaining reading, one of the foremost being the "Penny Magazine," which after attaining an unprecedented circulation seemed to raise up rivals, which in course of time vanished; but "Chambers' Journal," which started coeval with the "Penny Magazine," survives yet, and is regarded now amongst one of the best of the cheap serials. But gardening works were not neglected even then, and a rival to "London's Gardeners' Magazine" sprang up under the editorship of two of the most eminent gardeners of the day; but this after a brief period of usefulness seemed to merge into one devoted wholly to floriculture, thus paving the way for a weekly newspaper which appeared some time about the middle of the fourth decade of the century.

The extraordinary hard winter of 1838 following, scope was afforded for comparing notes of its effects. That winter was one of the hardest we have ever had. Even the hardiest class of German Greens suffered more or less, and on the moors and waste places in the country our native Gorse was very much cut. Hard winters also occurred in 1844-45 and 1846-47. A great impulse was given to gardening about this time by the cheapening of glass, for which the world has not been sufficiently grateful to the late Sir Robert Peel.

Other changes were taking place at the same time. Flower gardening on what has been called the massing system was introduced, and varieties of Geraniums, Verbenas, Petunias, Fuchsias, and other plants were raised in great numbers, while the old class of florists' flowers declined in public estimation. Horticultural societies then started up in many provincial towns; and the one at London seemed to be at the height of its glory, and was often referred to as giving laws to the others, as well as dictating matters relating to the quality of fruits and vegetables. About this time, too, the rapidly increasing use of the railway was found out, and London, which had formerly depended for its supply of vegetables and

fruits from the district immediately surrounding it, received large accessions from distant places; and the free-trade policy inaugurated at this time led to imports from abroad, which, though small at first, gradually rose to gigantic proportions; and as travelling became more easy our young gardeners had opportunities of visiting London and other distant places at less sacrifice of time and money than had formerly been necessary to visit the county town of the district where they lived.

Following on this came the first general Exhibition of 1851, of which gardeners have great reason to be proud, since the design for the building and its erection was confided to a gardener, after the learned profession by whom such things were usually erected had failed to produce a design at all applicable to the purpose wanted; and the able manner in which this was accomplished by its talented projector (Sir Joseph Paxton) is known far and wide. After the building was no longer wanted where it was erected, its removal to and the laying-out of the garden at the place which it now ornaments, forms an epoch in our history not likely to be easily forgotten. Coeval with this, gardening matters were not stationary elsewhere. Glass structures kept rising in all directions, and the hints and ideas which engineers and architects received from the Crystal Palace are seen in many of the finest railway stations and other similar erections in the kingdom; and the spirit of enterprise fairly launched displayed itself in many ways. Collectors of plants were sent to all parts of the world. The Himalaya and Californian ranges had previously yielded many of their floral treasures, and from the latter choice-flowering annuals had been sent by poor Douglas and others years before. But other fields opened out. Intercourse with China being permitted more freely than before, a host of new plants and choice shrubs were sent over, and the skill of our nursery-men and propagators soon placed them in the hands of the public; while older plants did not get neglected, but some that were thought to require the aid of a glass house to protect them in winter were now found to endure our winters, and added considerably to our outdoor display. Notable amongst this class were the seedling Rhododendrons obtained by crossing the half-hardy species from northern India with those we already possessed. Hence a mass of beauty that it would seem hopeless to surpass has been created, which has forced its way into places that were previously little better than wild unsightly wastes; and it is not too much to say that the Rhododendron is now planted where only the very commonest of our wild plants once found a home, and many a poor plantation is rendered gay by their flowers where only a coarse herbage once existed.

In like manner other plants have become common as the spirit of enterprise has kept pace with the introduction of new things, and I well remember the warm summers of 1857, 1858, and 1859 gave hopes that many tropical plants would do outdoors with us; and some who had tried the Chinese cattle-feeding plant, Sorghum, in 1859 were so elated with the success attending it that very large breadths were planted in 1860; but that disastrous year dispelled the delusion we had fallen into. The cold wet summer of that year, and the hard winter which followed, reminded us that the geographical position of Great Britain still remained where it had done for centuries, and that a fine temperate season could only be looked for now and then. Perhaps it is as well that it is so, for acquaintance with warmer climates informs us that they are not exempt from the cares and troubles which we are told is the fate of all mankind, and a knowledge of the difficulties we labour under has the natural tendency of increasing our industry to counteract these difficulties. But it is needless moralising on such matters here. Suffice it to say that after the cold wet season of 1860 we had two or three dry years, and the outcry for water was almost as loud as that which took place against it the year before; but a favourable season taking place in 1865 seemed to put all into good spirits again, and all went on well till the autumn, or rather winter of 1866-67 proved to us that our lot was still cast in the northern latitudes, and with the return of spring great complaints were made of the destruction of some choice Conifers. These casualties were perhaps after all more ideal than real, and attention being drawn to other matters, industry did much to compensate for the severe frosts which had been so destructive.

The events of the few past years are still in remembrance. The startling productions of monster bunches of Grapes were duly commented upon in the Journal by those well qualified to do so, and I note the very prominent position the Rose has taken

during that time. I think further comment may be left to all who have been able to read during that time, and I will close my notes with the usual compliments which the time of year calls forth, trusting that the new year we are entering upon may prove as favourable to all as everyone in his individual case can wish it to be; or, if otherwise, it may be consolatory to know that those who preceded us had their difficulties, without the many accessories to ensure a good result which we of the present day possess. Of the truth of this observation I feel certain that those who, like myself, have followed the calling a half-century or upwards will fully bear me out.—J. ROBSON.

### ELECTION OF PEARS.

SOME of your correspondents wished to know the names of the Pears that have done best; therefore I write the names of those I have always found best to come in succession. I state the months of ripening and names of the Pears:—

Citron des Carmes .....	July	Napoleon .....	Nov.
Jargonelle .....	Aug.	Louise Bonne de Jersey .....	Oct.
Windsor .....	Aug.	Duchesse d'Angoulême .....	Nov.
Dunmore .....	Sept.	Beurré Diel .....	Dec.
Autumn Bergamotte .....	Sept.	Beurré Bauré .....	Dec.

### VENN'S BLACK MUSCAT AND DUKE OF BUCCLEUCH GRAPES.

I SEE at page 496 one of your readers inquires about the first named of these Grapes, and from what I have seen of it I am quite of your opinion in thinking it will not keep so well as Lady Downe's or Alicante. When it was shown at South Kensington on the 8th of November last it was described as being very much "shrivelled." Now the first week in November is very early for any Grape with the slightest pretensions at being late to shrivel. About the middle of the same month I chanced to be visiting a friend of mine in the midland counties, who grows Grapes extensively and well. In one large house he had fine fruit of nearly every kind of Grape that is grown, and Venn's Black Muscat was the only one shrivelled and very badly so. It was remarked at the time that it corresponded here with those shown at Kensington, and fears were expressed that it would not prove a good keeper. No doubt some of your readers will have fruited it this season, and by this time they will be able to form an opinion of its keeping qualities, and perhaps "READER," as well as myself, would be very thankful to see some of your correspondents state their experience.

I am contemplating planting a vine shortly, and as I would like to introduce a few of the newer varieties of Grapes of known merit, would any of your readers recommend me to plant Duke of Buccleuch? By the time the Golden Champion was as old as the Duke we were pretty well informed of its merits or demerits, but of the Duke we have heard nothing, or I would not ask a place for this in your valuable columns.—AN ASPIRING AMATEUR.

### EARLY WRITERS ON ENGLISH GARDENING.

No. 24.

HUMPHRY REPTON.

HUMPHRY REPTON was born at Bury St. Edmund's, May 2nd, 1752. His father was Mr. John Repton, who for many years held the honourable and lucrative situation of Collector of Excise.

At a very early age Humphry was sent to the grammar school at Bury. He says, "I was too young to recollect much of those happy days, as they are always deemed by men, but of which children think differently, since the fear of the rod and the ferula, with the labour of the lesson and the task, are not less evils while they last than the fears of riper age or the anxieties of manhood. Perhaps the true difference between the life of a child and that of a man should be estimated by his power of enjoying pleasures rather than in his experience of evils."

From this school he was removed to the grammar school at Norwich, in which city his parents then resided, and thus

seven years passed in laying the foundation of classical knowledge; and he was rapidly rising to a high station amongst his schoolfellows, when, as he expresses it, "My father thought proper to put the stopper in my vial of classic literature, having determined to make me a rich rather than a learned man; perhaps wisely considering that if Solomon himself had not been the richest the world would scarcely give him credit for having been the wisest man." Large fortunes were at that time made by the exportation of the Norwich manufactures; and his father imagined, that by sending him abroad and directing his education in a new channel, he might in time rival those fortunate men who die possessed of £100,000. In the summer of 1764, therefore, his father and sister accompanied him from Harwich to Helvoetsluys, that the foundation of his future greatness might be laid by his learning Dutch in a school in Holland.

The school in which he was placed by his father was situated in the small village of Workum, and here he passed what would have been called a miserable twelvemonth by anyone of less buoyant spirits than his own; but he was one of those enviable beings who are so well described by Wordsworth as peculiarly—

"Blest with a kindly faculty to blunt  
The edge of adverse circumstances, and turn  
Into their contraries the petty plagues  
And hindrances with which they stand beset."

And his cheerful endurance was rewarded by a fortunate occurrence about this time, which made an entire change in his situation during the remainder of his stay in Holland.

With Mr. Zachary Hope of Rotterdam had been placed a sum sufficient to defray his school expenses; and a half-yearly payment had regularly been remitted by him to Workum, with some general inquiry as to the health and progress of the little Englishman. For this civility it was deemed necessary that the young gentleman should call and express his thanks. To most boys of thirteen this would have been an awful undertaking, but he possessed a naturally frank and open disposition, which, combined with the advantage of a strikingly handsome person, seldom failed to prepossess strangers in his favour. Perhaps these advantages were aided by the interesting situation of a boy thus thrown upon the kindness of strangers. From whatever cause it arose, however, this call of civility ended in an invitation to remain two days; and during that short time he became so great a favourite that it was declared "impossible to part with young Repton;" and thus for five months he was domesticated in Mr. Hope's family, a sharer in all the advantages of education with his only son, enjoying every pleasure and luxury which wealth could procure, and honoured by the friendship of other branches of that numerous and respectable name which, both at Amsterdam and Rotterdam, had established a kind of rank which vied with the proudest families of other countries.

For more than thirty years success beyond his hopes attended him in the profession of landscape gardening he had marked out for himself; and in the exercise of which he not only felt pleasure, but frequently had the power of promoting it in others. And to these blessings was added that of health, which had never known a day's interruption till the unfortunate night of January the 29th, 1811; when returning with his daughters from a ball given by Sir Thomas Lennard, his carriage was overturned, owing to an accumulation of snow in the road, he received an injury in the spine from which he never entirely recovered. For many weeks this accident confined him to his bed, deprived of all power of motion. In a situation so trying to one of his active disposition his mind still retained its energy, and his patient endurance of suffering and cheerfulness of spirits never deserted him for a moment. It was many months ere he was able to resume his usual pursuits; and there is little doubt that the loss of his accustomed exercise laid the foundation of that complaint which for the remaining years of his life occasioned him at times great agony, and which his physician pronounced to be angina pectoris. It was well known to himself (and he did not conceal it from those most dear to him), that the termination of this disease would be as sudden as it must be fatal; but the stroke was so long delayed that hope had almost raised a doubt in the minds of his friends as to the truth of that awful fate which he himself never forgot was hanging over him. On the morning of the 24th of March, 1818, he came down to breakfast, not more unwell than usual (the act of dressing had for some time been attended with a few moments of spasm in the chest), but he no sooner reached the breakfast room than he fell into the

arms of his servant, and expired without a groan. So instantaneous was his death, that before his son could hasten from the adjoining room his spirit had fled.

Perhaps there is no stronger proof of Mr. Repton's love for the beauties of nature than the wish he had latterly expressed, that his remains might be deposited in a "garden of Roses." To gratify this innocent fancy he himself selected the small

Fig. 80.—Humphry Repton

enclosure on the south side of the picturesque church of Aylsham in Norfolk. A simple Gothic monument records his name and age, followed by some lines written by himself—

"The tomb of Humphry Repton, who died March 24th, 1818.

"Not like the Egyptian tyrants—consecrate,  
Unmixt with others, shall my dust remain;  
But mouldering, blended, melting into earth,  
Mine shall give form and colour to the Rose;  
And while its vivid blossoms cheer mankind,  
Its perfume'd odour shall ascend to heaven."

For the above memoir we are indebted to the introduction to Mr. London's edition of Mr. Repton's works. His professional publications were "Sketches and Hints on Landscape Gardening," 1795; "Observations on the Theory and Practice of Landscape Gardening," 1803; "Inquiry into the Changes of Taste in Landscape Gardening," 1806; "Designs for the Pavilion at Brighton," 1808 (though these designs are said to have met the approbation of the Prince of Wales, and were, like the building afterwards erected by Nash, in a fancy oriental style, they were not adopted); and "Fragments on the Theory, &c., of Landscape Gardening," 1816, in which he was assisted by his eldest son.

#### MESSRS. JAMES VEITCH & SONS' NURSERIES, COOMBE WOOD, PUTNEY VALE, FULHAM.

"VEITCH'S" is a name familiar nearly to every gardener in Britain, and represents a business of almost world-wide reputation. The firm is, however, commonly thought of in connection with the rich collection of exotic plants at Chelsea,—the immense stock of Orchids, the choice "pitchers," and the almost bewildering miscellany of ornamental-foliaged and flowering plants more or less tender, more or less rare, and every one of them appearing as if it received special attention ministering to its health and cleanliness. But attractive, varied, and extensive as is Chelsea, it is but one section of the business of the "great firm."

My glance was a rapid one, extending over three nurseries during one of the dullest and shortest of days. Commencing at COOMBE WOOD I found not only a nursery of considerable extent well stocked and well furnished, but a nursery extremely

picturesque and possessing diversified features of natural beauty. It is less than twenty years ago since the late Mr. James Veitch, with that intuition for which he was remarkable, selected this site for this nursery. He had probably not only noted the purity of the air of the district and the altitude of the ground over the adjacent level, but had also, in all likelihood, observed the spontaneous growth of Holly in the hedge-rows. Conifers like a pure air, they are hardly grown on an elevation, and they become of the best constitution in a soil naturally suitable for them. This trio of advantages was found here. Mr. Veitch was also desirous of growing American plants largely, and the compost in which these plants best thrive is decayed vegetable matter. What position therefore would be more likely to afford this than the site of an old wood? A wood was therefore selected for the nursery, Coombe Wood. The jungle was penetrated and surveyed, and speedily the site was cleared of the trees and underwood. The particular part chosen was a great natural hollow of some thirty acres in extent, the entire of which is now occupied with shrubs and Conifers, growing as healthily as could be desired.

The whole of the nursery, however, is not in this "exalted hollow." Their upper and level portion is bounded by the public road, and from which the passer-by cannot but pause to admire the towering Conifers within, which are very conspicuous and ornamental. The most striking view is that down the principal or centre avenue of Wellingtonias and Araucarias alternately planted.

The planting of these fine specimens was directed by the late Mr. Veitch and Dr. Hogg, and the growth of the trees in the short period of fourteen or fifteen years is most remarkable. This is not a miniature avenue, but is quite 20 yards wide and 150 yards long. The Wellingtonias are growing about 8 yards apart, and the ground in front of them next the walk has been so planted that the principal trees are seen in their fullest beauty. At regular and wide distances on both sides of the central walk are planted choice Conifers of moderate growth and variegated Hollies. The ground at the bases of these is carpeted with hardy Heaths, and interspersed amongst the shrubs are Yuccas. The front lines next the path are composed of *Abies Clanbrasiliana* and other very dwarf Conifers, forming dense close rows of 2 to 3 feet in height. This thin but attractive mode of planting does not in the least obstruct the view of the principal trees—the

Wellingtonias and Araucarias—which are in robust health, and range from 20 to 30 feet in height. The formation of this avenue and the planting of the foreground was well conceived and carried out. At every few yards there is a distinct Conifer or choice Holly to admire, and looking between and above them are the handsome specimens which form its most commanding feature. The Wellingtonias and many of the Araucarias are singularly perfect, and the latter are never

injured by frost.

Arriving at the end of the avenue the scene changes. The view is no longer restricted, but we look over and across the hollow forming the principal part of the nursery, and cannot fail to admire the picture below, where nature and art are effectively combined. On the opposite hill are the remains of Coombe Wood, the masses of timber trees forming an appropriate background to the varied and large groups of the different-coloured foliage of the evergreens below. On the right is the mansion of Mr. Hammersley, (with the late Mr. Veitch's Japanese garden in front. On the left the hills of Surrey are visible in hazy blue undulations. In the centre of the hollow is an irregular meandering stream, in which are growing hardy aquatic plants, the banks being fringed with Bamboos, and towering above even their lofty canes are bold clumps of Pampas Grass supporting hundreds of feathery plumes. In the lowest portion of the hollow the American plants are arranged. Beyond and around them are the shrubs, and up the slopes of the hill surrounding are the Conifers. This arrangement

has been primarily adopted as best suiting the growth of the respective families of shrubs, and at the same time it is the most pleasing; it is an admirable example of natural grouping.

The nursery is traversed by winding walks with graceful curves, and every few yards reveal something fresh to admire. Few if any straight lines appear, and even the "specimen walk" has a graceful sweep. Let us pass along these twisting paths and note somewhat of the nursery's contents. It must, however, be a note *en masse*, for particular enumeration of many things which are noteworthy is out of the question. The specimen borders are planted with the choicest specimens of deciduous shrubs and evergreens. Here are the Japanese Maples, so elegant from their distinct foliage and effective from their rich colours. For choice places in shrubberies young plants of these are extremely suitable, and their effect

Fig. 81.—*RETINOSPORA OBTUSA GRACILIS AUREA*.

is heightened when associated with the lighter foliage of the popular variegated Maples. Of the Japanese Maples *Acer polymorphum*—the varieties *A. p. dissectum*, *A. p. palmatifidum*, *A. p. roseum marginatum*, *A. p. atropurpureum*, and *A. p. sanguineum* are all noticeable for their rich red and crimson tints or their chastely divided Fern-like foliage. Fears have been entertained lest the Maples should not prove hardy; but they are certainly hardy in the exposure of Coombe, for I noticed one shrub-like tree particularly which must have endured the severity of many winters. Differing greatly from the Maples are the Japanese Evergreen Oaks, which are also totally distinct from others of the genus to which they belong. *Quercus bambusæfolium* is exceedingly distinct; its foliage is 3 or 4 inches long and less than an inch broad and of a cheerful light green colour, rendering it conspicuous at a distance. It is perfectly hardy, and is worthy of a place on lawns and in shrubberies. Widely dissimilar is *Q. Burgerii* in three varieties, with large smooth glossy foliage resembling that of *Magnolias* or *Aucubas* rather than of Oaks, and is very imposing. We find here also an evergreen Plum, *Prunus ilicifolia*, a novelty which is being watched with interest. We next pause at a low dense-growing shrub with small foliage—*Osmanthus myrtifolius*. The leaves are acutely cordate and pointed,  $1\frac{1}{2}$  inch in length and half an inch broad, dark green and glossy and very ornamental. We next come to another new shrub of taller growth—*Azara microphylla*, which was introduced by Messrs. Veitch from Valdivia. There is no doubt of this shrub being quite hardy; it is also a free grower and graceful. Its leaves resemble somewhat those of the *Cotoneaster microphylla*, and the sprays bear small orange-red berries. The shrub is of upright habit with slender drooping branches, and is worthy of a place in select collections. Yet another new fruit-bearing shrub, *Hymenanthera crassifolia*, is conspicuous in the nursery. It also has some resemblance to the *Cotoneaster*, being of dwarf habit, having small foliage, and is laden with berries, but they are white—yes, white, and pearly as those of the *Mistletoe* and of the same size. For mountain sides and rockwork this must be regarded as a very select shrub where it can be viewed from below, and its numerous and curious berries can be seen to advantage. A flowering shrub of great promise, *Olearia Haastii*, is also being established in large numbers. It was introduced from New Zealand, and is quite hardy. It is most attractive and is exceedingly floriferous, every shoot bearing a bold terminal head of white fragrant flowers. For the front rows of shrubberies, or even for pots for early spring flowering, this is a decided acquisition. *Grevillea rosmarinifolia* is also most elegant. Its narrow foliage is very chaste, and the sprays are laden with small rosy scarlet flowers for six months of the year.

Intermixed with the evergreens and flowering shrubs are many choice Conifers. Effective is Young's Golden Juniper, a bright columnar shrub of great merit. *Juniperus pyramidalis stricta* is also exceedingly chaste, the foliage being of a silvery hue, and very dense and attractive. It is worthy of being grown in pots for select purposes of decoration. *J. drupacea* is also distinct and handsome from its larger twiglets of a glaucous hue. *J. argentea* and many others of the family are also represented by many handsome specimens. *Cupressus Lawsoni variegata*, which originated here, and *C. Lawsonii gracilis glauca* are constant in their variegation and must not be lost sight of, neither must the close green variety *C. L. erecta viridis*. The Umbrella Pine, *Sciadopitys verticillata*, is represented by many healthy specimens; this Conifer is so distinct and handsome that it must find its way into all gardens sooner or later, and the sooner the better. There are *Piceas* also, two of which not so generally grown as they deserve to be, *P. bracteata* and *P. polita*, the former conspicuous from its bold dark green leaflets, and the latter from its handsome habit somewhat resembling yet perfectly distinct from *P. pin-sapo*, in being of a bright grass-green colour. *Picea* or *Abies polita* is a Japanese Conifer of great merit and should be planted where trees of this nature are valued. *Abies Veitchii* and *A. tsuga Hamburgana* are also Japanese introductions, and give promise of being distinct and valuable additions to this ornamental genus. There are also *Cryptomerias* and *Retinosporas* in this rich border, and the shrubs, &c., are relieved with many fine clumps of the stately and beautiful Grass *Eulalia japonica*. This is elegant and handsome, the stems growing 5 feet high, and furnished with gracefully arching leaves 2 to 3 feet long and an inch broad, every leaf being boldly and clearly striped with white on a bright green ground.

This plant is perfectly hardy, and may be planted with confidence in any garden or shrubbery.

But we must look further down the valley, and here we come upon larger numbers of smaller plants of many of the choice subjects above named, and many more which are reluctantly passed silently by. Here are beds of all the best of the *Retinosporas* which produce a fine effect from the different hues of their foliage. Few plants than these are more valuable for winter decoration in vases on terraces, or in beds. The accompanying figure of *Retinospora obtusa gracilis aurea* gives a characteristic representation of this family, and speaks for itself of their slender elegance. Still richer in its golden hue, but of somewhat more rigid habit, is *R. obtusa aurea*. So golden is this variety that groups of it may be seen a mile distant—even a specimen growing in a quarter of Golden Hollies was conspicuous. In its young state the plant is of rather loose habit, but it improves as it attains size, and is one of richest in colour of all Conifers. No gardens where Conifers are grown should be without this cheerful plant. *R. plumosa* and *plumosa aurea*; *R. filicoides*, truly fern-like and feathery, *R. filifera*, *R. ericoides*, *R. leptoclada*, *R. lycopodioides*, and *R. squarrosa*, the latter having a distinct steel-like tint, were the most striking amongst these elegant miniature Conifers. These in their small state and in conjunction with singularly dwarf plants of the variegated *Euonymuses* (which are here largely grown), such as *E. japonicus aureo-variegata*, *E. aureo-marginatus*, *E. latifolius albo-marginatus*, *E. radicans variegatus*, and also *Cryptomeria elegans* if planted closely in choice flower beds near to the windows of mansions, dividing the colours with green-foliaged evergreens, would render these beds beautiful throughout the winter months. Plants for this purpose need only to be a few inches in height, and beds thus planted (as seen here) resemble at a distance a garden of flowers.

We pass on through acres of Hollies in all the select variegated forms, producing a rich effect. They are in plants from a few inches high to perfect specimens—standards, pyramids, and globes. Why are not these handsome glossy shrubs extensively planted? Too often only a very few are seen in gardens, and these so distantly sprinkled that their effect is lost, whereas if planted in groups and clumps they could not fail to add greatly to the beauty of lawns and shrubberies. This is "Holly time," and the value of these evergreens is seen in thousands of churches, homes, and gardens; but not many finer collections can be seen than in the home of the Holly at Coombe Wood. We are now in the centre amongst the Azaleas and Rhododendrons. These are alike numerous and varied. *Azalea pontica* and *A. mollis* are grown by thousands in all the best varieties; and Rhododendrons are yet more numerous, and are remarkable for their health and prospective profusion of flowers. The soil grows them sturdily, not over-luxuriantly; and the smallest of dwarf plants and handsome standards are alike furnished with buds almost on every spray.

Such is a general outline of this enjoyable nursery, or rather a portion of it, for there are other separate divisions. For instance, the stooling ground, where shrubs are increased by layers; *Magnolias*—*M. conspicua*, *M. purpurea*, the beautiful *M. Lenné*, and others being here noticeable. There are enclosures for seedlings, where Azaleas and Rhododendrons are covering the ground thick as grass. There are enclosures for cuttings of deciduous trees, others for Ivy (a rich and varied collection), in which *Helix arborea elegantissima*—unrivalled for winter bedding—cannot be overlooked. There are beds of *Liliums* and *Spiræas*, a remarkable collection of *Clematises*, and thousands of *Ampelopsis Veitchii* in pots to meet the constant demand. There are also Roses—an avenue permanently planted, besides the disposable stock; also a large and well-arranged block of glass structures, in which Conifers in countless thousands are propagated, and Roses in pots are in surprising number. It is here too where the prize Hyacinths are grown with which the firm has won so many honours. The bulbs are now potted, and are placed in the open nursery in their cocoa-nut fibre covering; by-and-by they will be placed in the houses to perfect their noble spikes—such spikes which when once seen can never be forgotten. Coombe is a fine nursery and well managed, a credit alike to its owners and their skilful and courteous manager, Mr. Dartnall. The nursery is a little over a mile distant from Norbiton station. It can be reached also from the stations of Putney, Kingston, Surbiton, and Maldon.

PUTNEY VALE.—This nursery is midway between Coombe

and Fulham. Putney Vale must be dismissed in the fewest words possible. It is devoted almost entirely to Roses, for which it was chosen from the strong nature of the soil. Some idea of the extent of this branch of the business is gathered from the fact that sixty thousand standard Briars are being planted for next year's budding, special prices having been given for stocks which are specially good. The boundary slip around this nursery is planted with Planes, Limes, and weeping trees. There are also collections of Pæonies and other herbaceous plants, but the body of the nursery (10 acres) is devoted wholly to Roses.

FULHAM.—This is not far from Chelsea, and is the dépôt for fruit trees. Twenty acres of fruit trees, and evidently not one too many. There are trees of all forms—standards trained and untrained, pyramids, bushes, and cordons. There are many vacancies, for the demand has been great; but there are plenty left, the policy being to grow in numbers sufficient to always secure a supply. Strawberries are also grown here, every variety being widely separated to prevent the chance of intermixing. The nursery is sheltered with a belt of young Planes. The demand for this, the "tree of trees" for towns, is very great, and provision is made to meet it. There are sundry glass structures—narrow houses for Oranges, Figs, &c., and a noble orchard house erected by Dennis of Chelmsford—a spacious and light structure, which grows Peach trees in pots to perfection.

Only one other feature of this nursery remains to be noticed, but this an important one. A prominent department of the business of the firm is the seed trade. All great firms dealing in seeds do something more than sell them. They prove them—prove not only their germinating properties, but their truthfulness to name and the quality of their produce. It is so here. Everything sold is proved, a staff of men being specially set apart for the work. Every stock is kept separate, and its quality is determined. Adjacent to this nursery is the root ground, where forty thousand crowns of Seakale and the same number of Asparagus are grown and sold annually.

Such is a sketch of the outlying branches of Messrs. Veitch's business, a business every section of which is conducted by men of proved competency, acting under the personal supervision of the active proprietors.—VISITOR.

### LATE-HANGING GRAPES.

In my greenhouse I have several rods of Black Hamburg Grapes, one of White Frontignan, one of Chasselas Napoleon (so called), and two of Lady Downe's. All have borne good crops this year. The Black Hamburgs have kept better than in any preceding year (under a new gardener), and not a few bunches are still hanging in excellent condition. The Chasselas Napoleon has also kept until now; but many of the berries of Lady Downe's are shrivelled and more or less disfigured with a sort of dull green mould, not in the least like that found on the few berries of the Black Hamburgs which have been attacked. I am unable to account for this, and shall be glad of information in order that I may guard against the recurrence of the mischief. I will state a few facts which may possibly have a bearing on the matter.

Towards the end of September I observed tiny drops of moisture like dewdrops on some of the berries in the morning. On calling the gardener's attention to this moisture he said the drops were the result of cracks in the Grapes. In accordance with some remarks which appeared in your Journal about that time I suggested that he might have kept the house too close at night. He now says the drops were only on a few of the berries, whereas many of them are shrivelled and disfigured by the dirty-looking mould. In summer, as a few of the berries were spoilt by spot, the lights were limewashed. The lime continued to adhere to the glass to the end of autumn, and I think injuriously intercepted the sun's rays and retarded the due ripening of the berries. Cracking is usually, I believe, attributed to excess of moisture at the roots; but the state of the border (inside the house) suited the Black Hamburgs. My impression is that the remedy against the "spot" unduly retarded the ripening process; but I cannot explain the connection between this and the cracking and the shrivelled and disfigured berries.

The White Frontignan bore a good crop, and its leaves seemed healthy, but most of the stems "shanked" before the Grapes were ripe; the shanking, moreover, occurred at a somewhat earlier stage than in previous years. I purpose cutting the rod down and grafting it with some other white sort less

difficult to manage, a sort with more flavour than Foster's Seedling. I am in doubt whether to graft, insert an eye, or plant a young Vine, and what Vine to have. I can give artificial heat. I shall be glad if some of your Vine-growing correspondents would give me the benefit of their experience and advice.—S. M. L. CARIN, *The Close, Salisbury*.

### JASMINUM SAMBAC FLORE-PLENO.

MR. ABBEY'S notes on indoor early winter flowers were very acceptable to me, as my chief want and desire is to have plenty of indoor flowers to cut during November and December. Many of the plants mentioned which I have not in my possession I will have at once. One plant which he names, however, I am very familiar with, and that is the one which heads this note. Of all flowering stove plants it is certainly the most worthy I know, as it not only flowers in early winter, but in every month of the year. Some time ago I had only one plant of it, and I can hardly remember seeing it out of bloom; and what is of equal importance the flowers are of great value, for they are pure white in colour and as sweetly scented as any of the Gardenias. In form the blooms are very like some of the Bouvardias. When grown in pots the plant must be trained to a trellis, but where cut flowers are the object it should be planted out and allowed to run in all directions. I have grown it in nothing but peat and sand, but lately I have tried a little decayed manure and loam in the mixture while potting, and I am beginning to think this is the best kind of compost to grow it in.—AMATEUR.

### THE DECORATION OF CHURCHES.

It is of floral decoration that I am writing chiefly; but at the same time it might be well combined with a limited number of evergreens in pots placed on either side of the chancel, and the same may be done down the aisles and the transepts, and they may not be out of place nearly in the centre of the church, as it is here they will produce a good effect if ranging from 1½ to 5 or even 4 feet in height, and placed tastefully. This I think may do away with nailing, tying, and wiring wreaths of evergreens to the walls and pillars and other places, which looked most suitable as in the ancient practice; but now in the modern practice I think more care and thought should be taken as to where driving of nails and looping of evergreen wreaths so as to deface and hide the beautiful work of ancient and modern carvers.

I find most effective scarlet and white if mixed together with taste, so as to form crosses, circles, and triangles; but whatever the form may be they must be flat or nearly so, and of any size, according to taste. For instance, if there be one vase only, I find that a scarlet centre margined with white in a triangular or pyramid form, backed up with Cypress or Juniper, with a few fronds of Maiden-hair Fern (*Adiantum cuneatum*) mixed in with them, has a good effect. The flowers used might be, for the centre, scarlet Pelargoniums, margined with Empress of India Chrysanthemum or Christmas Rose (*Helleborus niger*); or the centre may be Bouvardia Hogarth, with margin of *B. Vreelandii*, which are more lasting. The same may be said of Ericas and Epacrises of their respective colours, and the white Camellias mixed with the scarlet Bouvardia Hogarth; or if only one colour is used take the white Camellia or Christmas Rose set in the form of a cross, backed up with the above if there is only one vase used. But if there are three vases in use take for the centre one of the above, placing the other two on either side, which may be put up so as to form a white cross, with the corners (or groundwork) scarlet, and a backing-up of Cypress or Juniper, with a few fronds of Maiden-hair Fern. These look very effective; but avoid using blues or purples.—W. ROWE, *Gardener, Manor House, Histon*.

### NOTES AND GLEANINGS.

FEW winter-flowering stove plants are more dazzling in colour, not even Poinsettias, than *GESNERAS*, especially *G. cinabarina* and *G. exoniensis*. The former is perhaps the most useful, seeing that its flowers expand in a lower temperature, and they are also more fiery in colour than those of *G. exoniensis*. The foliage of both is of great substance, and is handsome from its plush-like appearance. Both are worthy of extensive cultivation where a temperature of 60° can be maintained. For flowering in winter the tubers require to be potted in June.

— ONE of the brightest and hardiest of CHRISTMAS FLOWERING PLANTS is undoubtedly the bright yellow Jasmine, *Jasminum nudiflorum*. As a hardy wall plant flowering in midwinter it has no equal, and its sprays of flowers are extremely useful for cutting. When grown in pots plunged in the open air plants are produced which are valuable for associating with evergreens, and rendering attractive places where more choice and tender plants could not be entrusted. This bright winter-flowering Jasmine might with advantage be more largely grown in many gardens than is the case at present. Cuttings strike readily, and small flowering plants may be produced during one summer's growth. A convenient mode of increase is by striking the young shoots in heat after the manner of *Verbenas*. This winter-flowering Jasmine is suitable for covering walls and trellises, and also by judicious pruning it may be produced in a bush form of growth, and thus grown it imparts a cheerful effect to shrubberies and pleasure grounds.

— THE WEATHER IN LONDON on Saturday was such as to suggest that a white Christmas was imminent. For many hours the snow fell, the flakes at night being of extraordinary size. Mixed with the snow, however, was rain more or less heavy, which, with the temperature a few degrees above freezing point, prevented the snow from accumulating, and on Sunday morning it was only an inch deep. On Monday morning (Christmas) it had all gone, and the day was of the usual autumn character—exceedingly dull with showers occurring. The cold, but not severe frost, still continues, but with protection and a little extra firing garden crops and plants may be comparatively safe from injury. The change from mild to colder weather may be a trifle unpleasant, but cannot fail to be beneficial in retarding the swelling of the fruit buds, which in many places are in a dangerously forward state.

— MR. DICKSON of Arkleton states that MADRESFIELD COURT GRAPE has done exceedingly well with him this year, and he esteems it as one of the finest exhibition black Grapes that he is acquainted with. Mr. Dickson also speaks in high terms of Mr. Bell's new Grape, Clive House Seedling, which was recently awarded a first-class certificate by the Fruit Committee of the Royal Horticultural Society. He has inspected the vineries at Clive House, and noted the robust character of the new Vine and its splendid crop of superior Grapes.

— A CORRESPONDENT writing to us in reference to the WEATHER IN SCOTLAND observes that the recent change from warm close days to cold east winds, with snow and rain alternately, will be the means of checking vegetation, which is in an advanced state and not anguring well for future fruit crops in the district of Eskdale.

— THE SWEET BAY (*Laurus nobilis*) is one of the finest of evergreens for lawns in places where it flourishes and is not injured by frost. We recently noticed some very fine specimens in the garden of W. Stevens, Esq., Springfield, Lower Tulse Hill. These bushes are somewhat egg-shaped, are about 15 feet high and 40 feet in circumference. They are almost perfect in shape and very handsome, Mr. Hall paying as much attention to these shrubs as to *Chrysanthemums*, which he grows so well. Mr. Hall can also evidently train pyramid fruit trees as well as flowering plants. The double white *Primulas* we found excellently grown, as well as Ferns and stove plants, also Grapes. It is not unusual to find good "all-round gardening" in small gardens, and this is one of them.

— TREE-PLANTING IN TOWNS FOR SHADE.—The law of New York State is encouraging; it is as follows:—Any person liable to highway tax that shall transplant by the side of the public highway any forest shade trees or fruit trees of suitable size, shall be allowed by the overseers of highways, in abatement of his highway tax, one dollar for every four trees set out; but no row of Elms shall be placed nearer than 70 feet, no row of Maples or other forest trees nearer than 50 feet, except Locust trees, which may be set 30 feet apart; and no allowance as before mentioned shall be made unless such trees shall have been set out the year previous to the demand for said abatement of tax, and are living and well protected from animals at the time of such demand.

— At the last meeting of the CHEMICAL SOCIETY Professor A. H. Church read a paper "On Colein," the red-colouring matter existing in the leaves and stems of *Coleus Verscheffeltii*. Colein when pure is an amorphous substance of a brilliant crimson colour, unalterable by exposure to light or by the

action of dilute acids; alkalis, however, alter it rapidly. Its alcoholic solution when freshly prepared is of a bright red colour, but, in common with that of some other red-colouring matters, it rapidly fades until it becomes almost colourless. This is due to a combination of the colein with the alcohol, the red colour being immediately restored on the addition of a little acid.

— IN a manuscript history of England in the notes on 1660 is stated—"October. A great river cut out of the maine land in St. James's Parke, a very broad one."

— THE UNUSUAL SCARCITY OF HOLLY BERRIES has been a great disappointment to those who derive much pleasure from church and room decoration at Christmastide. It appears that the Holly blossoms could not withstand the frosts of spring any more than could the fruit blossoms. The Mistletoe fruited very freely from flowering occurring somewhat later and when the frosts had passed.

## DOINGS OF THE LAST AND WORK FOR THE PRESENT WEEK.

### KITCHEN GARDEN.

As we have not been able to do anything to the kitchen-garden quarters opportunity has been taken to clean and surface the walks with fresh gravel. This work can be done very well in wet weather, as the roller presses down the gravel quite as firmly as it does at any other time. Before placing any fresh gravel on the surface we had the walks forked over to the depth of a couple of inches. When this is done so much fine gravel is not required. Our kitchen-garden walks were well made ten years ago, and they have scarcely involved any expense since. They were of a good depth at the centre, in some cases 12 inches, gradually becoming shallower towards the sides. The soil at that part could not be removed more than an inch or two, as it was required for the Box edging; but to prevent worms from working through it into the walks some lime rubbish was placed over it and beaten down firmly with the back of a spade. At the deepest part a layer of brickbats was placed to drain away the water, and this it has done most effectually. In wet districts it would be necessary to have drain pipes to carry away the water, but these we have not found to be requisite. Over the brickbats came a layer of coarse gravel, this also being rammed in firmly, and lastly 2 or 3 inches of fine gravel, which was levelled carefully, the highest part being the centre; after repeated rolling the work was complete. These walks ought not to be used for wheeling barrows upon, or for conveying rubbish or produce from the kitchen-garden quarters. Borders which ought to be planted with fruit trees or the smaller kitchen-garden crops may run parallel with the walks, and at the back of the border alleys 2 feet wide will be found most convenient for wheeling upon. When it is necessary to pass from the alleys on to the walks neat scrapers should be fixed at convenient places, so that there may be no excuse for carrying soil on to the gravel. All draining operations may be carried out in wet weather. We would have the drains 4 feet deep, 3-inch drain tiles in the bottom, with 3 or 4 inches of rubble over them, and over the rubble turves with the grass side under, or, failing these, some long litter.

Garlic and Shallots may be planted when the weather is fine, and it is well to see that damage is not done to Broccoli from frost or wet; all plants showing their heads should be protected by bending a leaf or two over the centre. The early Peas have come strongly through the ground, and the carbolic dressing has effectually prevented the mice from eating the seed. We shall the first fine day draw a covering of soil over the rows.

It has been previously stated that heated pits are best adapted for forcing Asparagus, but many gardens are not furnished with such convenient structures, and those who are require them for other purposes. Good forced Asparagus is produced from dung beds, or from beds of stable manure and leaves in equal proportions, and when leaves cannot be had to mix with the manure we have found long tussocky grass, which we can spud out of marshy ground, an excellent substitute. This is mixed with the manure in the same proportion as the leaves. The whole ought to be thrown lightly in a heap for two weeks before using, and be turned over once in that time. If the bed after it is made up heats violently it is better to wait until it partly subsides before placing in the roots. Some turf cut and placed with the grass side down will also keep down the heat. Place the roots in thickly, and cover them with fine soil. All such work may be done in wet weather, also placing Rhubarb and Seakale to force in Mushroom houses or other structures.

### VINERIES.

Our early Vines have not yet started into growth, though the buds are prominent. A moist atmosphere is kept up, but the night temperature is not permitted to exceed 50°, and this is quite high enough until the growths have pushed an inch, when

it may be increased to 55°, and when the leaves are formed to 60°, and 65° a little further on. Unless the roots of Vines are forced by bottom heat they do not begin moving until the leaves are formed, and to force hard before this is a tax upon the energies of the Vines which, if persisted in, would ultimately ruin them. When it is seen that the growths are shooting vigorously the Vine will endure a very high temperature, but it is better that the minimum in the case of Muscats does not exceed 70°, and for Hamburgs 65°. The following varieties may be mentioned as requiring Muscat heat:—Gros Colman, Alicante, Lady Downe's, Gros Guillaume, Trebbiano, White Nice, Syrian, and True Tokay. In the Hamburg temperature Royal Ascot, Black Prince, West's St. Peter's, Royal Muscadine, Buckland Sweetwater, Golden Hamburgh, Foster's Seedling, Duchess of Buccleuch, Duke of Buccleuch, Golden Champion, and Dr. Hogg will succeed. Lady Downe's does well in the same temperature, although it is named in the list of those requiring more heat.

There is such a manifest control over the roots of Vines in pots that they may be forced more rapidly than those planted in the open border, and the roots of which have gone over the bounds allotted to them. It is also of importance sometimes to push the Vines on rapidly, in order to have the Grapes in by a certain time; and if the pot Vines suffer it does not matter much, as it is more profitable to grow a good crop the first season and to destroy the canes after the crop is gathered.

Late Grapes still hanging require daily attention, as it very much depends upon the care that is taken of them as to heating, ventilating, removing decaying berries and leaves, whether the fruit will keep long in a presentable condition. Another matter is the sweeping-out of the houses. In some cases this is in charge of a careless boy, and he will, by raising clouds of dust, in time cover the berries with it, and so render them unfit for the dessert table. It is well to keep every part of the house clean; but when sweeping is necessary it ought to be done gently, and not oftener than once a week.

#### PEACH HOUSE.

We alluded on December 7th to starting the house, and instructions were given as to watering, syringing, temperature, &c. Some may even have started the earliest house before that date. Peaches will not stand such a high temperature as Vines, not that the trees will not thrive, for they will grow rapidly, and the more so because the buds will drop to the extent of endangering the crop. Early in the season 55° for a night temperature is the safest, a little ventilation being left on at night. A very dry atmosphere is not the best at setting time; dry by day and moderately moist at night is the best. The flowers will not be likely to set well without a little help; they should either be brushed over once a day with a camel-hair pencil, or they may be fertilised by gently rapping the wires twice a day with a stout walking-stick, when the pollen will be distributed.

#### PLANT STOVE AND ORCHID HOUSES.

We have repeatedly urged the importance of destroying all insect pests at this season of the year, when they and the plants are in an inactive state. It is a good plan to fumigate the house once a fortnight from the beginning of January until the end of February—that is, if many of the plants have been infested with thrips. When Orchids and other tender stove plants are in growth they are not unlikely to be injured by the fumes of tobacco smoke, and even at this season of the year the operation must be performed with caution. We wash the leaves of any plants that are attacked by brown or white scale and mealy bug with rain water in which as much soft soap has been dissolved as the leaves will endure with impunity.

The roof of the stove must not be shaded with climbing plants; it is a great mistake to leave too much leafy growth between the plants on the stage and the light at any season, but especially during the winter. In the first place nothing can be more unsightly than a quantity of shoots trained one over the other. This should never be; we would as soon train the lateral growths of Vines one over the other as of flowering plants, for in neither case can success be attained. An Allamanda trained to the roof was cut back to within a few feet of the base of the rafters. A plant of Bougainvillea glabra was removed to the greenhouse some time ago. The roots have been kept dry since, but the leaves have not fallen to a very great extent. Clerodendron Thompsonii and C. Balfourii we shall always winter in a house where the temperature does not fall below 55° for the future. It is not safe to place the plants in the greenhouse, as we have lost them in that way in previous years.

Caladiums, although the soil is as dry as dust in the pots containing the tubers, are safer under the stage in the stove than anywhere else. There are some Amaryllises in flower at present which were placed in heat some time ago, but the flowers are very much inferior to what they ought to be.

In the plant stove nearly all the plants are better with the temperature as low as it is safe to have it for the next three weeks, and as the daylight increases the temperature may rise with it. We have removed Anthurium Scherzerianum to the

Cattleya house, where the temperature is more suitable than in the plant stove with 60° at night; from 50° to 55° suits this plant better during the winter months, and the spathes are brighter and of a more leathery texture with the lower temperature. Little need be said about Orchids. Keep the plants clean and at rest; any unnecessary excitement from heat or moisture is injurious to them. The East Indian house should range about 60°, Cattleya house 50° to 55°, and cool house 45° to 50°, rising 5° by day.—J. DOUGLAS.

### TRADE CATALOGUES RECEIVED.

Dicksons & Co., 1, Waterloo Place, Edinburgh.—*List of Gladioli.*

François Lacharme, Quai de la Vitriolerie, Guillotière, Lyons, France.—*List of New and Choice Roses.*

A. M. C. Jongkindt Coninck, Tottenham Nurseries, Dedemsvaart, near Zwolle, Netherlands.—*Trade List of Fruit Trees, Roses, Perennials, Aquatic Plants, &c.*

### HORTICULTURAL EXHIBITIONS.

SECRETARIES will oblige us by informing us of the dates on which exhibitions are to be held.

CRYSTAL PALACE (Artificial Flowers and Fruit). March 17th. NEWCASTLE-UPON-TYNE. March 21st and 22nd. Messrs. J. H. French, Benwell House, and J. Taylor, Rye Hill, Hon. Secs.

GLASGOW. March 28th and May 28rd. Mr. F. G. Dougal, Sec.

LEEDS (Spring Show). April 2nd and 3rd. Mr. A. Walker, Neville St., School Close, Leeds, Hon. Sec.

WISBECH. June 28th. Mr. Charles Parker, Hon. Sec.

TONBRIDGE. July 18th. Mr. W. Blair, Sec.

ISLE OF THANET. August 30th. Mr. C. D. Smith, Hon. Sec.

### TO CORRESPONDENTS.

\* \* All correspondence should be directed either to "The Editors," or to "The Publisher." Letters addressed to Mr. Johnson or Dr. Hogg often remain unopened unavoidably. We request that no one will write privately to any of our correspondents, as doing so subjects them to unjustifiable trouble and expense.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, and should never send more than two or three questions at once. All articles intended for insertion should be written on one side of the paper only. We cannot reply to questions through the post.

BOOKS (*F. Cannon*).—There are no separate works on the subjects you mention. Those which include them are Martyn's edition of "Miller's Gardener's Dictionary" and London's "Encyclopædias." (*A Reader*).—We have no Stove Manual, but our "Indoor Gardening" treats of stove plants generally with other subjects. It may be had by post for 1s. 7½d.

FRAMES (*J. E.*).—The Acme frames are patent, and are to be had of Mr. B. Looker, Kingston-on-Thames, to whom your letter has been forwarded.

EVERGREENS FOR SEASIDE (*Frank*).—The Tamarisk (*Tamarix gallica*) and the Japan Spindle Tree (*Eucynus japonica*) are hardy, and are grown abundantly along the south coast of England.

REMOVING CONSERVATORY (*W. Booth*).—Legally the conservatory could not be sold if attached to the freehold, and you have bought what previously belonged to you. The tenant, we think, cannot compel you to remove it, as he erected it.

FUNGUS (*A. B., Bromley Common*).—The name of your woody fungus from the Cherry tree is *Polyporus ignarius*. The species is common on Cherry, Plum, and other trees.

BEST FORM OF LAPSTONE KIDNEY (*J. R.*).—It is too much to ask us to say which is the best. Try as many sorts as you can and select. Penn's Perfection is certainly very handsome. The following sorts have all been proved by the Royal Horticultural Society in their trial grounds to be forms of Lapstone—Yorkshire Hero, Haigh's Seedling, Headley's Nonpareil, Huntingdon Kidney, Pebble White, Rixton Pippin, Perfection, and Ashted Fluke.

PLANTING LATERAL CORDONS ON FRUIT BORDER (*C. J. D.*).—As you intend to plant Strawberries between the cordons and walk, the distance between would be a matter of taste. If you plant but one row of Strawberries let them be 6 inches from the edge, and the cordons 2 feet. The cordons ought to be trained about a foot from the surface of the ground. Apples are better for such purposes than Pears. Of Apples the best are Early Margaret, Irish Peach, Kerry Pippin, Margil, Ribston Pippin, Cox's Orange Pippin, Mannington's Pearmain, Old Nonpareil, Keddestones Pippin, and Sturmer Pippin. The above are dessert sorts. Of kitchen Apples—Kewick Codlin, Hawthornden, Cellini, Bedfordshire Foundling, Dumelow's Seedling, Rymer, and Gooseberry Apple are suitable.

DESTROYING WIREWORMS (*Henry Thomson*).—Soot and lime may check the increase of these pests, but we have found both ineffectual in destroying them. The best remedy would be to burn the surface soil; but as yours is shallow burning would destroy its staple, and might otherwise not be convenient. Gas lime distributed over the surface at the rate of one peck to sixty square yards, and pointing in lightly, is mostly an effectual application.

HEATING SMALL FRAME (*A. Macdonald*).—Your question was answered in our number published December 7th.

LABOUR REQUIRED IN GARDEN (*J. B.*).—So much depends on the arrangements of a garden, and the requirements of its owners, that it is always difficult to judge with precision from particulars of extent merely. For the garden you describe we think seven men and two boys necessary—i.e., two

men and a boy for the kitchen garden, the same for the houses and frames two men for shrubbery and flower garden, and one man for the walks and drives. That is, of course, a rough apportionment of labour, the outdoor men especially being employed in any portion of the garden where the work at any time becomes pressing.

**RUSSIAN TRANSPARENT APPLE** (*W. Simmons & Co.*).—We will endeavour to procure the information you require.

**ORANGE "BLOSSOM"** (*A Reader*).—We presume your tree is an Orange (*Citrus aurantium*), which will succeed in a greenhouse, and should have a light and airy situation, and be copiously supplied with water during growth, but avoiding over-watering, allowing the soil to become dry before giving any, and then a thorough supply. In winter keep rather dry. Three parts turfy loam, with a part of old cow dung or leaf soil and sand, is a suitable compost. Provide efficient drainage.

**YEW HEDGE DECATING** (*Idem*).—The bottom of the Yew having been destroyed by the Laurel, and the Yew cut down, will put out shoots from the stem, the dead branches being cut away. It will be some years, however, before the young shoots will have grown so as to form a well-furnished hedge. Privet would form a hedge in a short time, but the Yew is much the best, though very much longer in forming.

**SEEDLING GERANIUMS** (*Idem*).—Plants from seed sown last July will flower during the coming summer. We should plant them out (or plunge the pots about an inch over the rim) in May in an open situation, and not very rich soil, for seedlings grow very much to leaf as compared with plants from cuttings. Lobelias will winter in a frame provided they are kept from frost; but we should keep them in the coolest part of the greenhouse, and near the glass. Saxifrage do well in gritty loam, moist but well drained. They are best grown on rockwork with full exposure, taking care to avoid over-dryness during hot weather.

**FUNGUS (Almer)**.—Your Fungus is known as the "Jews-ear" (*Hirneola Auricula-Judea*), usually found on the Elder and Elm.

**NAMES OF FRUITS** (*R. M. A.*).—*Apples*.—1, Pomeroy; 2, Gravenstein. *Pears*.—1, Quire rotten; 2, Beurre Rance. Others not identified. (*W. H.*).—Your Grape is the Black Morocco, which has been distributed under the name of Kempsey's Alicante. The bunch sent was remarkably well set, this variety being proverbially a shy setter.

## POULTRY, BEE, AND PIGEON CHRONICLE.

### LANGSHANS.

"H. J. B." writes for information about Langshans. He says they appear to be "a cross between the Cochins and Brahma," and requests our opinion on the matter. Honestly, we think they are nothing but cross-bred fowls, Black Cochins entering principally into their composition. We do not want to raise any discussion on the matter, and we are glad that such an uninteresting subject has hitherto been kept out of these pages. Our opinions are shared by the majority of fanciers, and we can well imagine how breeders and exhibitors of twenty or thirty years' standing laugh at those who uphold the true breeding and distinctive points of Langshans. Wonderful stories are told of them: week after week one of their admirers advertised that they were "allied to the wild Turkey;" we only wonder someone else did not say they were first cousins to Ostriches. Be they, however, mongrels or a distinct breed, one thing is certain, and that is, weedy Black Cochins have done duty for Langshans in their own classes, and Black Cochins breeders advertise and sell their refuse birds as "birds of the Langshan type," and as these are purchased as Langshans, whatever their origin may have been, such birds will soon be wanting in those peculiarities which Langshan admirers claim for their breed.

We believe there are some who assert that the Langshans made the Black Cochins, and not the opposite; but we know for a fact that Black Cochins have come over from Shanghai of the most perfect Cochins type, and that no Langshan blood was in those specimens. We were the means of putting into Mr. Darby's possession that wonderful Black hen which won all before her for two or three seasons, and which has never since been surpassed in merits, and there was about as much Langshan blood in her as there is in a Sparrow. Undoubtedly, in our opinion, what they are is a cross between a Black Cochins and some white-skinned plump fowl, and hence the white flesh and more abundant meat which their admirers claim for them as their distinctive points. We know how easily feathered legs and black colour are perpetuated, and so these birds breed true as far as they can breed true, being weedy-looking black-feathered Cochins. We can see no difference in external appearance between them and bad Cochins, and we looked at them very closely at the Palace, where we know one winning pen of so-called Langshans contained actual Cochins, and we are as certain that one or two of the Langshans would have won cards if entered among the Cochins. This being so, we fail to see any advantage in keeping up the farce as to the supposition of their being a new breed. Imported they may have been, and imported they still may be, but not in Great Britain only are breeds of poultry crossed; and until the admirers of this composition can bring forward more certain proofs of what they claim for them, we would recommend them to be silent on the subject.

Being cross-bred birds they may have properties which make them useful for the table and other domestic purposes; but to

maintain that they have no Cochins blood in them is as ridiculous as to try and make out their Turkey connection. One who can believe that can believe anything, and we can full well understand their being deceived. We are told that the Judge who awarded the prizes in the Langshan classes at the late Palace Show was ignorant of their points, and so made a mistake in his awards. We should have been curious to see to which pens their champions would have given the prizes, for there was hardly a pen but had some Cochins point more or less developed. Their place, undoubtedly, is in that class which we sometimes find in agricultural societies' schedules—viz., for "Any table variety of cross-bred fowl," and then the judge would be able to take meaty breasts and fleshy thighs into consideration, in which we hear this new variety so greatly excels. We expect very shortly to hear that as in Cochins, so Langshans are to be found of many colours. We look forward to the day for some reasons, as we have now some weedy Whites and Buffs, which gradually are turned into pasties; but to find a market for them at 20s. each would indeed be delightful, for as it is they are only worth table poultry prices.

At the last Bristol Show we saw in the Selling class for cocks a bird which was evidently a cross between an Asiatic and a Dorking. It was feather-legged, single-combed, white-fleshed, and of moderate size, and we could only pity the possessor who had invested 5s. for displaying such a mongrel. Later on in the day a very celebrated Cochins breeder and exhibitor came to us and said, "You must, of course, notice in 'our Journal' the new breed." We said, naturally, "What new breed?" "Is it possible," cried the Cochins breeder, "you have not seen the Silver-Grey Langshans? I am expecting representatives from Worthing and Bromley every minute to see this last new wonder, and to get them classes at Wolverhampton." This shows what Cochins men think, and this, too, from an exhibitor of fifteen years' standing.

This is all we have to say. Useful for culinary purposes Langshans may be, productive layers they possibly are, but mongrels—sad mongrels, they are beyond doubt.

We mean to enter into no controversy, and these pages are in future closed to a discussion on the subject. We leave that to our contemporaries, who also, however, seem to be weary of the matter. When the wild Turkey connection has been proved we will gladly print the family tree. In the meantime we recommend those who want a cross-bred fowl to try the first cross between a Brahma and a Dorking, and to leave the "Longshins" alone.—W.

### BEDALE SHOW OF POULTRY, &c.

The third annual Show was held at Bedale in the Drill Hall, on Tuesday, the 19th inst. The place was too small for the purpose, the entries being good; and the light, in consequence of the crowded state, was very defective, and yet it is due to the Society to say this is the only place at disposal for the purpose.

*Game* were a capital show, Brown Reds carrying the cup off, these being chickens, the pullet quite young, but grand in every particular, Brown Reds being second. In *Game* other than Reds the winners were Duckwings, and all very good in colour and stylish. *Dorkings* a grand class, the cup for the next section going to the first-prize old birds. *Cochins* poor, except the winners; and *Brahmas* a fair lot. In *Gold-spangled Hamburgs* the winners were two grand pens, but the Silvers were not equal to them. The best of this lot were left out, the pullet having undergone some smearing process that had stuck all its feathers together. The cockerel was a gem. *Gold* and *Silver-pencils* were but moderate, the cup going to *Gold-spangles*; and in the next section *Spanish* took the place of honour. In the *Polish* the prizes were awarded to *Goldens*; first old and second young. One pen of *Silvers* could not be judged; the cock having indulged in a bath it was impossible to judge of his crest qualities. In the *Variety* class first were *Black Hamburgs*, second *White Leghorns*, and third *Crève-Cœurs*. In *Game Bantams* first were very smart *Black Reds*, second *Piles*, and third *Brown Reds*, many others securing very high commendations. In the *Variety* class of *Bantams* first were *Silver Sebrights*, second and third *Blacks*. In the *Selling* class first were *Black Hamburgs*, second *Partridge Cochins*, and third *Rouen Ducks*. *Turkeys* and *Geese* were very large, and good in all particulars. *Ducks*.—*Aylesburys* were very good, and the two winning pens of high quality and well shown. *Rouens* good as regards the winners. The *Variety* class was a very good one; *Mandarins*, *Carolinas*, and *Black East Indians* were the winners.

*Pigeons* good for the amount offered. *Carriers*—first *Dun*, second and third *Black*. In *Pouters* first was a *Blue* hen in fine order, second *White*, and third *Black*. In *Jacobins* a good *Yellow* was placed first, with a *Red* second. *Tumblers* were a fair class; first and second were *Almonds*, and third *Kites*. *Fantails* were a fair class, and the winners *White*, but there was one grand *Blue*. In *Turbits* first was a little *Blue*, good in all particulars, although some preferred the highly-commended bird of that colour. Second was a capital *Red* hen. The *Selling* class was poor.

**Cage Birds.**—Of these there were some good specimens, particularly the first-prize Crested Norwich and the first in the Variety class, a Yellow Belgian of more than ordinary merit.

There was a fair entry of *Rabbits*, but as a rule all were poor except the winners. In Lops first was a Black-and-white doe, 22½ by 4½; second Fawn-and-white, 21½ by 4½; the third, 22½ by 4½, was in very bad condition. In the Variety class first was a Silver-Grey, second Silver-Cream, and third Himalayan.

**POULTRY.**—*Game.*—*Black-breasted and other Reds.*—Cup and 1, C. Venables. 2, W. & H. Adams. 3, R. McDonic. *Any other variety.*—1, Holmes & Desner. 2, W. Robson. *Chc.* C. Venables. *Dorkings.*—Cup and 1, T. P. Carver. 2, J. S. Crowther. 3, R. F. T. Froud. 4, J. Newall. *H. Wilkinson.* *COCHINS.*—1, H. B. Proctor. 2, Miss Cotes. *BRAMAS.*—1, W. H. Garforth. 2, G. Pounder. *Whc.* H. Wilkinson. *HAMBURGS.*—*Golden-spangled.*—Cup and 1, R. Keenleyside. 2, W. Atkinson. *Silver-spangled.*—1, H. Stanworth. 2, Holmes & Desner. *Golden-pencilled.*—1, T. & G. Kidson. 2, W. Holmes. *Silver-pencilled.*—1, Rev. J. N. Williams. 2, W. Jopling. *SPANISH.*—Cup and 1, J. Thrush. 2, H. Dale. *POULARDS.*—1, J. T. Froud. 2, G. Nicholson. *ANY VARIETY.*—1, W. Waddington. 2, W. Shields. 3, R. L. Garnett. *Chc.* Lady Bolton. *BANTAMS.*—*Game.*—1, T. H. & A. Stretch. 2, and 3, J. Robson. *Chc.* W. Atkinson. *H. M. McDonic.* *Smith and Atty.* Mrs. C. Porter. *W. & H. Adams.* *Any variety except Game.*—1, T. P. Carver. 2, W. & H. Adams. 3, F. T. Crowther. *Chc.* R. H. Ashton. *Holmes and Desner.* *BARNDORF FOWLS.*—*Crossbred.*—1, J. Braithwaite. 2, Dr. Umpleby. *SELLING CLASS.*—1, R. L. Garnett. 2, J. Cass. 3, T. Scoby. *Chc.* R. McDonic. *Holmes & Desner.* *T. P. Carver.* *TURKEYS.*—1, Mrs. Kirk. 2, G. Mangles. 3, W. H. Garforth. *Chc.* Mrs. V. Bird. *GEES.*—1, G. Pounder. 2, F. J. Crowther. 3, and 4, J. Robson. *Chc.* E. Gibson. *Chc.* J. Cass. *ROUENS.*—1, F. G. Kayson. 2, Mrs. Crossley. 3, W. H. Garforth. *Any other variety.*—1 and 2, J. Johnson. 3, R. Wiles, jun. *Chc.* Rev. A. Webb.

**PIGEONS.**—*CARRIERS.*—1, W. & H. Adams. 2, G. Sadler. 3, Joy & Robinson. *PORTERS.*—1, Joy & Robinson. 2, T. Gallon. 3, G. Sadler. *JACOBIANS.*—1, G. Alderson. 2, J. ## GUILDFORD POULTRY SHOW.

This Show, in connection with the Surrey Agricultural Society's Show, was held on the 11th and 12th inst. in the Green Market, Guildford. The Show is not confined to the county of Surrey, though the majority of exhibitors are local. The entries fell short of some former years, but we thought the quality improved. We heard that several exhibitors had their entries refused as being late, which is a loss to a show of this kind, and we recommend the Committee not to close their entry book so long beforehand another year.

*Dorkings* were, as usual in this neighbourhood, good. The cup for the best pen went to a grand pair of Dark chickens, first in their class. They might well be in this position, as the cockerel is the Palace cup bird, also first at Bristol, and he was shown with a pullet worthy of him. The second-prize pen contained a good cockerel, but a pullet dark in feet. The third-prize cockerel was a fine dark bird with dark feet again. In the next class for adults a square old-fashioned pair of Rose-combed birds were first. We fear this breed is nearly extinct. Second were large Silver-Greys. Third Darks of large frame with white feet, but the cock out of condition. Whites were not so numerous as formerly. First a fine well-shaped pair, well-known winners; second very fair, third moderate. We were very sorry to see a great falling-off in the number of Cuckoos from former years. We hope this useful breed is not ceasing to be the speciality of this neighbourhood. In lieu of fifteen or twenty pens three were shown. The pullets in the first and second pens were good dark birds; the second cockerel was the largest, but too light in colour; third were single-combed birds. *Cochins* were all shown in one class. First were Partridge; a fine hen with an under-feathered cockerel. Second middling Whites; third a well-shaped Buff cock mated with a small pullet. Pen 27 (Roumieu) contained a fine Buff cockerel. *Dark Brahmas.*—First were chickens, the cockerel remarkable for beautiful orange legs (we think we saw him at the Palace), the pullet well pencilled. Second the best hen in the class, with a cock too brown on wing. Third a good pair; the hen, however, very brown. Light Brahmas were as a class good. First a very pretty cock, but hen with scarcely any leg-feathering, though capital neck hackle. Second and third were fair birds, but creamy in colour. *Spanish* were poor; the first pair alone deserved notice. *Game.*—First were Brown Reds, the cock a beauty, the hen rather too high in comb; the cup for the best pen other than Dorkings went to them. The Judge first awarded it to the first Golden-pencilled Hamburgs, but as their owner (Mr. Cresswell) was the donor of this cup it was passed on to the next best pen. Second, fair Black Reds. *French.*—One pair of Houdans alone put in an appearance. *Hamburgs.*—The Golden-pencils in this class were capital, and carried all before them. In the first pen the cockerel was very rich in colour, uniform throughout. Second a good pair, but

cockerel more bronzy in tail than the first. There was a large entry of *Game Bantams*. First pretty Piles, second Black Reds, the cockerel badly dubbed. Various pretty birds in this class were thrown out from being badly matched in legs. The first Black Bantams in the Any other variety class were capital; a special prize was awarded to the cockerel. In *Ducks* Rouens carried off all the prizes in the first class, Black East Indians in the other. *Geese* were fine. *Turkeys* magnificent.

The *Pigeon* class was a most interesting feature in the Show; seven prizes brought thirty entries. On the whole far better birds than we ever saw at such a show. First were grand Black Turbits; second and third Archangels, worthy to be in Bingley Hall; fourth Yellow Turbits. Good Blue Owls and fair Black Carriers came in afterwards.

The Judge was the Rev. R. S. S. Woodgate, and his awards seemed to give general satisfaction. In spite of bad weather the visitors were numerous on Tuesday morning, many farmers being among the company. Such shows do much good, and we wish them success. We published the prize list last week.

## DUNSE SHOW OF POULTRY, &c.

The first Show was held at Dunse in the Corn Exchange on the 14th inst., and considering that it had not been well advertised the entries were good, and we have no doubt but that this will become an annual event on an extensive scale. The pens of the Edinburgh Gymnasium were used, and were very good and well placed. The birds were judged catalogue in hand.

First on the list were *Dorkings*, of which there were some good birds, the first Dark Greys especially. *Cochins* a bad lot; but the winning *Brahmas* made amends. *Game* had except the first Black Reds. In *Spanish* were some good birds; the first-prize cock very deep and smooth in face. *Hamburgs* were poor with the exception of two pens; and *Bantams*, *Game*, very bad; the variety Bantams one of the best classes in the Show, Blacks winning all the prizes. *Ducks* were good in entries, the Aylesburys being the best class of poultry in the Show, while in Rouens there were but two good pens, and in the Variety class Black East Indians and White Calls won. *Turkeys* and *Geese* very good indeed.

*Pigeons* had eight classes, and were better than the poultry. In Tumblers a very good Short-faced pair of Blue Balds were first and Red Mottles second, one pair of Almonds being too pale, and in another case the hen had bad eyes. Fantails bad; and only the first pen of Ponters of any value, but these were good stylish Blues. Jacobins a good class; first Red, second Yellow, and third Black. Nuns good; and in Owls were some capital headed birds, especially the first-prize Blue cock. Turbits a very good class, all being noticed; first Yellow, second Yellow, and third Blues. In the Variety class first were White African Owls, second Fire Pigeons, and third Blue Dragons.

The prize list we published last week.

## THE BIRMINGHAM COLUMBIAN SOCIETY'S SHOW.

The members of this Society held a special Show in the long dining-room of the White Horse Hotel, Congreve Street, in order to provide an additional attraction for friends and visitors to Bingley Hall. There was a very large attendance, which included a number of the élite of the Pigeon fancy, who thoroughly enjoyed the treat provided for them, and so much so that the general expression was heard on every side, "I never spent a more enjoyable evening, or saw a finer show of its kind." Down the centre of the room, on a long table, were arranged in two rows twenty-three large cages 3 feet long by 2 or 2½ feet wide, specially made for the occasion by one of the members, Mr. J. M. Bott. It folds up into a large flat box about 2 inches deep, which forms the bottom of the cage when in use. A long row of gas jets (gratuitously provided by Mr. Grice, another member) extended down the centre of the room above the cages, and furnished a brilliant light in every cage. Perhaps the greatest attraction of the Show was the grand display of Carriers, the general quality of which was unexceptionable. To criticise the merits of the various collections of this variety would be a task both difficult and invidious, even if we had space to do it; and we will therefore only say that they were shown by Mr. T. Hallam, the splendid condition of whose six old and six young Blacks was specially admired; Messrs. Allsop, J. Siddons, G. Jordin, C. Cook, S. Lingard, Key, and Cartwright. Antwerps of all the colours were shown by Messrs. H. Wright, Grice, Forrest, Mapplebeck, and Key. Mr. H. Pratt showed four Pouters up to his well-known quality; Mr. Gough, a pen of beautiful Satinets; Mr. Ludlow, one cage of the charming foreign varieties which he has made so famous, as well as a cage of a variety he calls "Red Indians," and which are something after the style of Red Dragons, but of a brilliant colour. Mr. Bott and Mr. W. B. Mapplebeck showed collections of the several varieties of flying Tumblers, some of them remarkably

handsome; Mr. Royds, a cage of admirable Jacobins containing two Reds, two Blacks, two Yellows, and two Splashes, the latter particularly striking; Mr. Booth, a pretty cage of foreign Owls and Shortfaces; and last, but by no means least except in size, we must mention a dozen Almond Tumblers shown by Mr. T. Hallam, of the quality for which he is so well known as a breeder, and which could not have failed to please the most fastidious either as regards head properties or colour. Amongst them was the charming little Palace cup cock, which is a study for an Almond breeder. The general arrangements of the Show reflected the greatest credit on the courteous and indefatigable Secretary, Mr. H. Allsop.

## THE MANAGEMENT OF THE LOP-EARED RABBIT.

DURING the last few years foreign breeds of Rabbits have greatly improved their position in the estimation of Rabbit fanciers; and whereas a few years since no other breed than the Lop was kept for showing, now a great deal of attention is paid to the smaller but no less interesting varieties. Lops, however, still hold their position as the first among fancy Rabbits, and hence I have selected them for the first of a series of papers on Rabbit breeding and rearing.

There are several points relating to the keeping of Lop-eared Rabbits that require attention, and several of them have caused much unnecessary controversy. The ears have always been considered one of the most important features in the breed, and although the other points are now receiving more attention and are more highly valued, it is not because the ears are to be neglected. Twenty-two inches from tip to tip of ear measured across the top of the head used to be considered a great length, but considerable improvement has been made lately in this respect; and although 22 is still considerably over the average, 22½, and even 23½ are sometimes attained. Twenty-four inches has only been touched upon two occasions, and then only by London judges.

To attain these enormous lengths recourse has to be had to heat, and it is the proper regulation of this that is one of the chief points to be considered in management. If the temperature be too high the animal's health will considerably suffer, whereas if it be too low the ears will not be long enough. Some writers advocate 80° or 90°, but 60° or 70° at the most is quite high enough for health. Ear-stretching used at one time to be resorted to to increase the length of ears, but it really tends to shorten them by breaking the delicate fibres of which those organs are composed. It is not so much practised now as formerly, but at one time it was an almost prevalent practice.

In breeding the first thing to be done is to select the parent stock. Do not let the desire to have great length of ear overcome the necessity of having health and strength. Select a strong doe with ears not under 20, or, if possible, say 21 or 22 inches. Let the buck's ears be not less than 22, and as much more as possible, and above all be careful that both parents are strong and in good condition. If you are breeding for colour see whether the Rabbits have been produced by parents of the same colour as themselves, and if not whether there were any in the litter like either parent. This is necessary, because in some strains Rabbits do not all keep to colour. If you want black-and-white a black doe is best, and a black-and-white buck. As a general rule, it is best to breed for broken colours with self-colours, or else the offspring will not be heavy enough in markings.

Having selected your parent stock and paired them, the next question will be the doe's hutch in the which she is to kindle. This should be constructed with the ordinary two compartments, and on the double-floor principle. Let it be fairly roomy, but not over-large—say 3 feet or 3 feet 6 inches by about 2 feet, and the sleeping room something under a foot. Between the real and artificial floors there should be a space of an inch or more, and the former is best constructed of stone, slate, or metal. This space I think is best left open, but I have seen it advocated to fill it up with sawdust, so that the urine could percolate into it and throw off a warm vapour. I should hardly think this would be very healthy, and if it be done for ventilation holes should be bored through the top of the hutch so that the foul air can escape at once. This hutch should be placed in an outhouse or shed so constructed as to perfectly exclude all draughts, but yet to afford sufficient ventilation. The floor should be covered with asphalt or cement, as the wet will soak into any other substance and cause an unhealthy vapour to be constantly rising. If there is not a floor of this description the next best is a layer of sand 2 or 3 inches deep, which can be renewed three or four times a-year. Sand or gravel is decidedly better than soil, but both are more or less unhealthy. The roof should be moderately high.

As the doe's time of kindling draws nigh, that is towards the end of the fourth week, liberally supply her with fine straw and sweet hay, and she will soon make her nest of it. You may rely upon her being with young if she tears the hay up and carries it

about in her mouth. Having made a nest of the straw and hay she will line it with fur from her own breast, sometimes in her zeal laying herself almost bare. At the time of kindling the doe is often afflicted with excessive thirst, to appease which she will sometimes eat one or more of her young. A saucer of milk or water will alleviate this.

Arrange your breeding so that you will have a nurse doe kindling at about the same time. When your Lop doe has kindled about a couple of days seize an opportunity when she is feeding to have a look at the young. Even at that age you will be able to tell plainly enough which are the best marked. Select two or three of these and leave them with the doe. The remainder remove, and substitute for your nurse doe's litter. Great care should be used over this operation, as if the doe note the change she will unmercifully attack the new comers. Shut her from the young a few hours before changing them, and feed her with very moist food so as to give her a great flow of milk. Do not admit her into the dark room until the fresh young ones have been there some little time, so that they will have settled down. Then admit her, and after the young have once drawn her milk there will be no more difficulty, and she will tend them the same as her own. Keep the front of the hutch covered up the first week or two so as to keep the young Rabbits warm. Supply both mothers liberally with good nourishing food, not omitting to give them plenty of a succulent nature. If you want length of ear and good size for show purposes, the longer you have the young with the doe the better, so long as she does not fight them. When this occurs often, if she be put to the buck she will be quite peaceable again. As soon as the young begin to feed give them soft flesh-forming food, taking care not to derange the bowels, as this will keep them back more than anything. Keep them with their mother till at least two months old, and as near three as you can. Even if you exceed three it will only tend to increase their size. Remember that at this time their ears are capable of tremendous growth, and your work is to increase that growth as much as you can. Sometimes both ears do not fall evenly, one being inclined to be upright or to fall over the face. The course in that case is as follows:—Put the Rabbit in question on your knees and gently work the ears, *not pull them*, till they assume the correct position. Let this be repeated daily as long as necessary. There need be nothing cruel in the action. Pulling will do more harm than good, and if only gently worked the Rabbit scarcely notices it, and *frequently will continue eating during the operation*. Feed liberally with crushed corn, and vary the kind as often as you like, for just as you prefer a change from beef to mutton, and back again, so does bunny like a change in his diet occasionally. Wheat, oats, and barley form three very good flesh and size-forming foods. For a treat, and to put flesh upon their bones, give an occasional—say once a-week or fortnight—mess of split peas. Let these be first scalded in hot water and left to soak several hours; then let the water be poured off, and a very little milk be added. An occasional feed of brewers' grains is also good, but neither of these two last should be given too often.

Supply liberally with green stuff. Take care that no poison gets among it, as several herbs are noxious to the Rabbit. Lettuce, cabbage, carrot tops, soft and tender grass, young corn, tares, all kinds of clover, trifolium, and lucerne, endive, parsley, (beware of the hemlock, which has a round and spotted leaf, and is poisonous); sow thistles, young grass, and several other herbs may with safety be given. The amount need not be very limited, provided always that it is gathered dry, and left a little in the sun or warmth before being given. No green stuff must ever be given wet, and if it be gathered wet and then dried, the process will take out nearly all the goodness. Supply good hay *ad libitum*. This is one of the cheapest and best foods that you can possibly give to Rabbits, although when it is used in abundance there must also be a good supply of succulent food, or there will be a tendency to constipation. Roots are very good. Swede and all kind of turnips and carrots may be given with great advantage.

Lop Rabbits should be kindled in the spring or early summer, so that less artificial heat will be required. If, however, you have late litters be sure you keep your temperature uniform in the winter, and supply with warm food. Bran mash is good when given warm, but is not very strengthening. If the addition of a little oat or barley meal be made it will improve it greatly, and make it wholesome, nourishing, and at the same time palatable.

It should be hardly necessary to speak of the importance of cleanliness in breeding. The effects of neglecting this all-important duty are sometimes seen at once, the young dying off rapidly; but even if this be not so, the effect will be there ready to show itself when opportunity shall occur either in the form of disease or in stunted growth. The necessity of keeping air that is regulated to 60° pure, should be apparent to all. If the very necessary precaution be neglected the air will assume a fetid and noxious smell that will make it horrible to enter the rabbitry. The hutches should be cleaned out once a day, and

scoured once a week or so. The refuse should be carried out of the place at once, and not allowed to accumulate. It is best to let the wet run from the hutches into a bucket or into a drain. If the former plan be adopted, empty the bucket daily or oftener, and keep a little disinfectant in it; and if the latter, swill a bucketful of water down occasionally. In either case keep plenty of disinfectants about the hutches, and a little charcoal suspended from the roof with string will often lessen the smell. If these precautions be attended to the rabbitry should smell sweet and will be healthy.

I will not leave this subject without considering the question of a stove for heating. If in a town, or any place where gas is cheap, I can recommend nothing better than a jet of this kept burning constantly. This will be quite sufficient to keep up the temperature if the room be dry and snug. Another very good stove is one constructed to burn paraffin. This will be found both cheap and effective. If coals are burnt, a common open stove will not do, because it will be impossible to keep it at a uniform temperature. A closed stove will fulfil its work very fairly, but hardly so well as paraffin or gas.

This is the treatment recommended when young Rabbits are being reared for showing. When reared for breeding, however, I should advise the total abolition of all the heat, and if bred in the summer the more they are kept out of doors the stronger and hardier mothers they will make. If bred out of doors care should be taken to construct the hutch so that there cannot be the slightest opportunity for draught, and the front should not be made so open as is the case in hutches of an ordinary nature.

In purchasing Rabbits for breeding it is just as well to note which way they have been reared. Bear in mind that a 20-inch outdoor-bred doe is far better for your purpose than a 21-inch indoor-bred one. The latter are often very poor at breeding. Also to observe how many were reared with it, and to select from those litters that were few in number, as in that case you will be more certain of hardness and strength.—GETA.

## HIVES.

PERHAPS no one is better able to defend himself upon anything he has said than Mr. Pettigrew, who has so lately advocated the use of the improved cottager's straw skep by the poor labouring man, or those who can spend comparatively little time with their bees. Many of your readers will ever feel deeply indebted to that gentleman for his plain systematic teaching on the management of bees in large straw skeps—a kind of hive many can have for the making, with supers, haddles, and all complete. And it is the labouring cottager who is so deeply interested in this question of bee-keeping; therefore hundreds there must be who can hope for nothing else, and perhaps need nothing better, all things considered. There may be many a splendid "little move" in bee management to produce such grand results as one witnessed at the Alexandra Palace this season, but even those in favour of Stewarton or bar-frame hives can hardly make it necessary or desirable to write down the hive at work in the hands of hundreds or thousands who cannot appear at a London palace.

In endeavouring to do something of the sort, your correspondent "A RENFREWSHIRE BEE-KEEPER," in your issue of November 30th, tells a strange story, no doubt quite true; but if all kinds of hives were to be judged in like manner, what one is there which may not be condemned as useless? Your correspondent says, "On stand No. 10 stood a swarm of the preceding year hived in two 7-inch Stewarton boxes, and side by side on No. 11 a swarm of the same year located in a roomy straw skep, both possessing queens of 1874, each having an overflowing population." After bestowing care, of course both equal, to obtain the greatest amount of super honey from both, the result was—No. 10, Stewarton, gross weight (four octagon supers) 68 lbs.; No. 11, straw skep, one Abingdon glass not sealed out, 21½ gross; large straw skep, with its 8-inch eke starving. The Stewarton no doubt was crammed completely, although we are not told so.

Now I venture to ask your correspondent a plain question. Does he, as an intelligent bee-keeper, believe that the great difference in these results is due to the kind of hive used? While the business of No. 10 was going on, what could the "overflowing population" of No. 11 have been doing? And yet they did not swarm, so they lost no time in that way. Perhaps your correspondent will kindly inform us how they lost so much time.

The season of 1875 was so bad here that bees in any kind of hive in the months of June, July, and August were in a starving state, and almost depopulated by wind and wet. In the autumn I united as much as possible, and fed vigorously, taking care of all good hives of comb for the following season. Most of us know something of the difficulties of last summer, autumn, winter, and spring, but no sooner did June appear than the bees went to work with a will truly admirable. On June 18th two first swarms were hived into 18-inch straw skeps full of good combs, and on the 23rd two others were hived into skeps also full of clean healthy combs, and perhaps something larger. It was a sight not to be forgotten to watch the going in and

out of these thousands of busy labourers in hives so liberally offered with roomy alighting boards and entrances, 4½ inches wide and 1 inch deep. They increased in weight so rapidly that I was induced to weigh one, and found that in thirteen days it reached 69 lbs. gross. One stock, which swarmed June 23rd, threw off a cast ten days after, and twenty-three days after the first issued I turned out the old stock into a good hive of comb; the bees went to work the next day as if nothing had happened. The old hive and contents weighed 54 lbs., and in August the first swarm, hive and contents, 85 lbs.; the turnout, ditto again, 61 lbs.; cast 22 lbs. (for some reason this did not do well); total 222 lbs. gross; and I believe many of the bees went back. The three stocks of bees sugar-fed are now in splendid condition.

In August I drove out the bees from five straw skeps into others quite empty and sugar-fed, uniting bees from cottagers' condemned stocks when I could, as so often advocated by Mr. Pettigrew, to keep up strength. The gross weights of these hives and their straw supers were as follows:—

No. 1	hive, 64 lbs.	....	super 16 lbs.	.....	80 lbs.
" 2	" 70 lbs.	....	" 25 lbs.	.....	95 lbs.
" 3	" 80 lbs.	....	" 21 lbs.	.....	101 lbs.
" 4	" 74 lbs.	....	" 11 lbs.	.....	85 lbs.
" 5	" 85 lbs.	.....			85 lbs.
373 lbs.			73 lbs.		446 lbs.

These weights (not much to some people perhaps) are sufficient to show that the old straw skep is not the despicable thing to be avoided as your correspondent would have us believe, for it is worth remarking that nothing was done to obtain these results which the poor labourer could not do who leaves his home at five o'clock in the morning, with instructions to his wife that if such a swarm should come off to-day put it into such a hive. On his return at 6 p.m. he is delighted that it did come off and is all right.

"A RENFREWSHIRE BEE-KEEPER" will do us good service if he will conduct fair trials of different kinds of hives, and show the one which comes within the reach of poor people, and can be managed by either man or wife as occasion requires, and which will enable him to obtain super as well as first-class run honey in greater abundance than can be done by the use of the 18-inch straw skep as advised and worked by Mr. Pettigrew.—W. J. C.

## INTRODUCING QUEENS—TWO SOVEREIGNS.

YOUR valued contributor "B. & W." recently narrated an interesting case as to how he had introduced an Italian queen twelve hours after the removal of the black queen, by means of a broken wineglass and piece of perforated zinc. She was well received by the bees at first, but subsequently the disturbed state of the hive caused him to return their own black queen; yet notwithstanding, young yellow-jackets have since made their appearance, and your correspondent thinks the phenomenon may possibly be accounted for by a joint reign.

First as to the mode of introduction. In the days of my novitiate I found many queens dead on the zinc from the coldness of the night air causing the workers to fall back towards their centre. Queens ought to be caged between the combs to be safe, and for a much longer period than twelve hours. The disturbed state of the stock arose from the Italian queen being then encased, and on having a choice the workers simply preferred the Italian, which alone reigns.

I will illustrate this by a parallel and more striking case from my own apiary last year, and singularly enough the heroine of my tale was the joint occupant of a throne. The ragged wings of my imported Italian queen bespoke her having seen service, but she was still amazingly prolific. The workers persistently built royal cells, which were as regularly excised. Her majesty seemed to have made up her mind to abdicate the throne, as she exhibited not the slightest interest or paid any attention to the royal cells building (a most unusual circumstance), when suddenly a princess burst upon the scene hatched in some odd cranny; she treated her with sovereign contempt, and for many weeks this state of matters continued. On my return after a short absence I was sorry to find my old valued queen had disappeared, most probably expelled, but regret much I had missed a sight of her departure.

Shortly afterwards I deposited the young queen of the observatory to make room for an imported successor, and, not wishing to destroy her, removed an older queen from one of my Stewarton stocks, and after she was missed caged the young queen from the observatory therein. On the third day after I excised several royal cells, and so soon as the hive had quieted down I liberated her; but shortly, from the disturbed state of the workers, judged she was encased, raised the frames, and found it even so. I again caged her for a similar period with no better results. A third term of like imprisonment only resulted in yet another encasement. I was by this time so heartily sick of my perverse favourites that I abandoned her majesty to her fate, and

I introduced their own queen, which was gladly welcomed. The following morning in passing round the garden, and still preserving a kindly remembrance of my poor young queen, I thought I would like to look upon her remains. Nearing No. 5 I found a single dead bee on the landing board as I had expected, and a queen; but on turning her over on the palm of my hand she bore a striking resemblance to the old queen. In a trice the cover was off and the frames raised, and to my great joy the thrice-rejected was now the free and accepted reigning monarch of my Stewarton hive. She still survives, and her numerous progeny gleaned some of my finest supers the by-past season.—A RENFREWSHIRE BEE-KEEPER.

### ANOTHER YEAR'S EXPERIENCE.

In bee-keeping, as in other things, there is a connection between cause and effect—management and results. In every year's experience we find that the apiarian who attends to the details of management and plays his part well is most successful. Though bees require less attention and care than most other creatures useful to man, they do need some attention at certain times and seasons, and therefore should not be forgotten. Stories are told of bees living continuously in the cavities of trees and roofs of houses. That bees live occasionally in such places a few years without attention from the hand of man I can readily believe; but having long doubted that honey bees are natives (originally) of Great Britain, I have given but little credence to the stories alluded to. That the cavities of trees, &c., once occupied by defunct swarms are haunted by bees and attractive to fugitive swarms seeking homes or habitations we all know, and hence the likelihood of mistakes having been made as to unbroken successions of occupation of hollow trees and cavities by swarms. The fickleness of our climate and seasons make it necessary for the bee-keeper to care for and attend to the wants of his little favourites. Bees need protection from wet and cold in winter, and must have food in times of famine. Every year's experience goes to prove that bees out of doors cannot be too well covered during the winter and spring months. A certain amount of warmth is necessary for the comfort of bees. In the absence of this warmth they cleave and cluster very closely together and remain all but motionless. In cold weather they are helpless creatures, often perishing in clusters in the centres of their hives within 6 inches of their own honey. Though bees should be well covered in winter, they should not be stimulated and encouraged to breed then by artificial feeding. If bees have not power to feed themselves in cold weather how can they attend to their young? Winter feeding is attended with risk and danger, inasmuch as it tends to promote breeding; and if cold weather prevents the bees from giving proper attention to the brood in the cells it becomes foul. Besides, it is more natural for bees to rest during the months of November, December, and January. In the south of England they may be encouraged to breed in February, and north of Manchester March is soon enough in ordinary seasons. In wintering bees in greenhouses we find that they seldom leave their hives when the mercury of the thermometer is below 50°, and at 55° (temperate) they begin work on whatever flowers they can find.

In seasons early and favourable for honey-gathering I have generally found that the swarming system of management gave the best results in both honey and stock. By it more space is occupied, more bees bred, more honey gathered, and fewer swarms lost. In late unfavourable seasons those who repress swarming have generally the greatest success. Those who acted on the non-swarming principle this year reaped the largest harvests. In considering this question of bee-keeping, the aims of the bee-master, the pasturage ground, and the markets for honey have all to be remembered and compassed. In large apiaries it is well to follow both systems of management. Amateurs, too, who keep a few hives only, and want a supply of honey every year, will seldom be disappointed if they manage half of their hives on the non-swarming, and the other half on the swarming, principle.

During the months of September, October, and November of this year I created more stocks by sugar-feeding than on any former occasion. In this work I found that when the hives were well filled with bees comb-building went on rapidly, and that when only about half filled with bees comb-building went on more slowly; and towards the end of the season very little brood appeared in the centre combs of these syrup-fed stocks. What beautiful pure virgin combs were built! What a temptation to fill supers of comb thus for another year! If I were going in for a swarm of supers every year I should utilise the bees of honey hives in autumn in filling as many supers with comb as I could by sugar syrup. Not, of course, to sell the syrup for honey—that would be fraudulent and dishonest, but simply for comb-building. From 20 lbs. or 5s. worth of sugar a good swarm will fill a super with comb, capable of holding at least 30 lbs. of honey. But how could the syrup be extracted without injury to the combs? This could be done by bees only, and experience

would discover the best way of letting the bees do it. In extracting the syrup from one super they could and would build combs in another, though not to the same extent. Thus the syrup would be used again and again in filling with combs additional supers. A word to the wise is enough. With plenty of supers, filled or nearly filled with pure white empty combs, a very great amount or weight of honeycomb could be obtained from an apiary in a favourable season. This theoretical suggestion will, I think, commend itself as practical to the bee-keepers of England. I am not aware that any important discovery in bee history or management has been made during 1876. The introduction or notice of "sectional supers" deserves honourable mention. They doubtless will be found very convenient for the retail sale of honeycomb. I commend them to the notice of all who keep bees for the production and sale of comb.

I regret that the season has passed without anybody in this country coming to the front to prove the superiority of one kind of bee over another. For four or five years I have done everything I could to induce the patrons and advocates of Italian bees to pit them against the common sort, and I am still willing to do what I can to bring the matter to the test of a fair and satisfactory trial. The fairest test I have ever seen reported took place in America this year. In that case the blacks beat the yellows, leaving them a considerable distance behind. I earnestly hope that arrangements will be made for a trial of strength next year in this country. The experiment is worth a little sacrifice, and if several gentlemen will come forward with their aid and advice a most interesting and profitable contest will be the result. I have never uttered a word against Italian bees, neither have I ever seen a shadow of proof of their superiority. Having the greatest possible confidence in the working and breeding powers of the common English bees, their industry and hardiness, I can scarcely be expected to discard them in the absence of satisfactory proof that a better kind of bee exists.—A. PETTIGREW.

### REMARKS.

20th.—Hazy early, raining forenoon, sun shining through the rain at 1 P.M.; rather heavy rain after; fair in the evening.  
 21st.—Very fine day throughout, and starlight night; wind rather cold.  
 22nd.—Slight frost; splendidly bright about 1 P.M.; very fine all day and night.  
 23rd.—Fair but dull early, dull all day; snow in evening, and very heavy snow and rain in the night and early morning.  
 24th.—Snow thick on the ground at 9 A.M.; very dark and slightly thawing all day; rain again at night.  
 25th.—Very dull, snow still on the ground and falling again for a short time about 10 A.M.; very damp and cold till the evening, when it became drier.  
 26th.—Fair but dull, though frosty, and the air very nipping from the north-east; rain and snow after 8.30 P.M.  
 Mean temperature generally about 5° lower than during the previous week. The special feature has, however, been the excessive fall of rain and snow.—G. J. SYMONS.
